

Introduction to Cellular Automata

BASIC CONCEPTS

- Modelling using „**cellular automata**“, short **CA**, is a microscopic simulation method
- Cellular automata can be **imagined** as a coloured grid observed dynamically

Although this is a very simplified image of a CA, keep it in mind to understand the formal details of this concept

- Cells

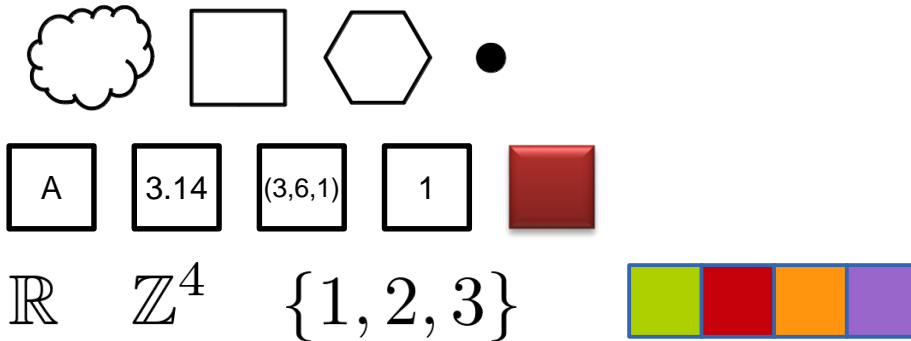

- Cells

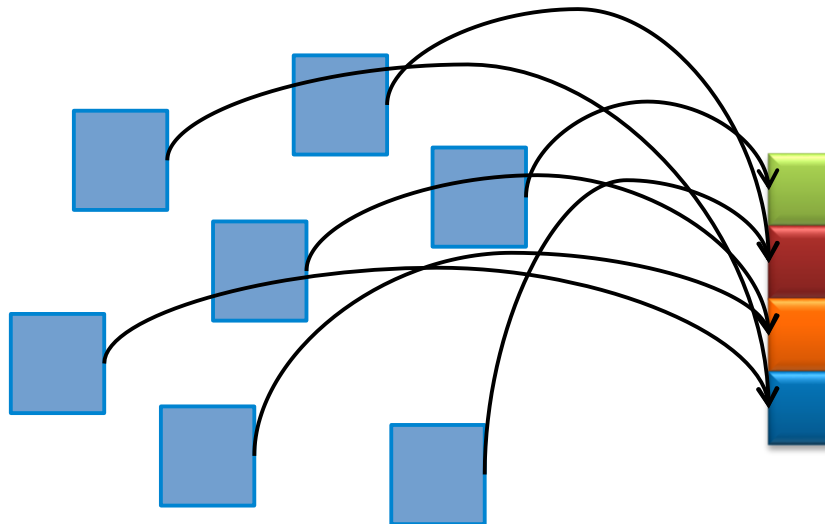

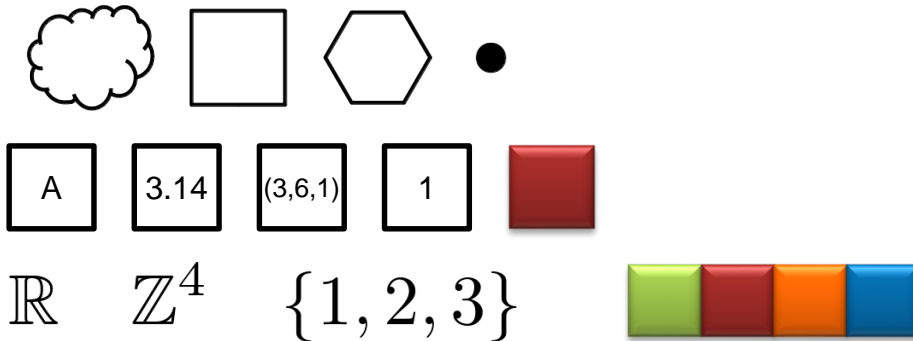

- Notations: cell, entity, node
- Cells are passive: no internal dynamic, only container for some information
- Each cell has some state.

- Cells
- States
- State-space

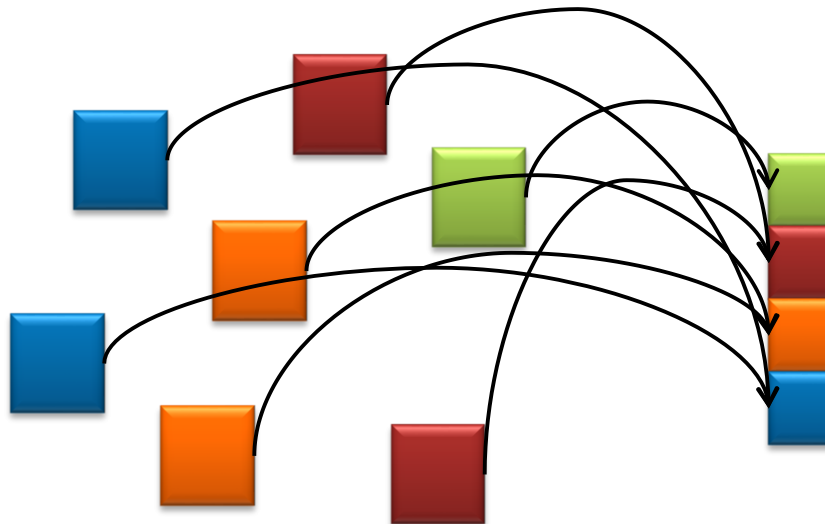

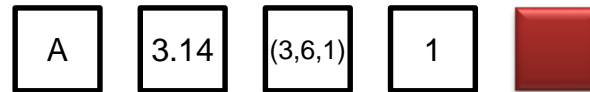

- Every Cell has a state
- There is always some space \mathbb{S} that contains all possible states. It is usually called state-space.

- Cells
- States
- State-space

Every cell has a state from a common state-space

- Cells
- States
- State-space

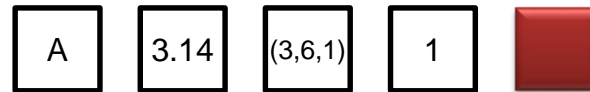

Every cell has a state from a common state-space

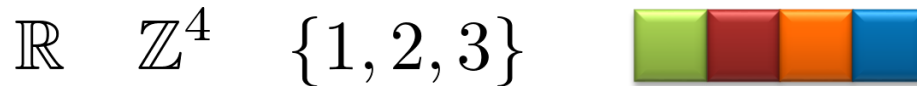

- Cells

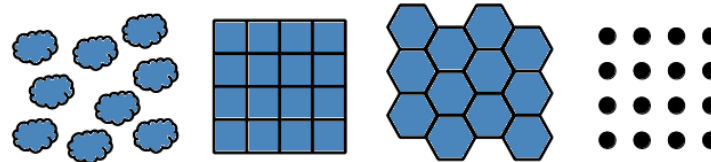

- States

- State-space

- Arrangement
(Cell-space)

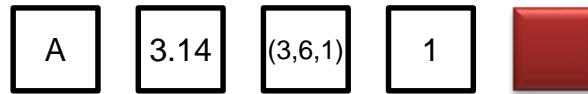

- All cells are arranged on some lattice structure: the „cell-space“ – in the simplest case, a rectangular grid.
- There is some index mapping that maps some subset of $I \subset \mathbb{Z}^d$ onto each cell

Components of a CA

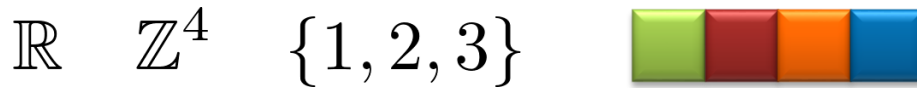

- Cells

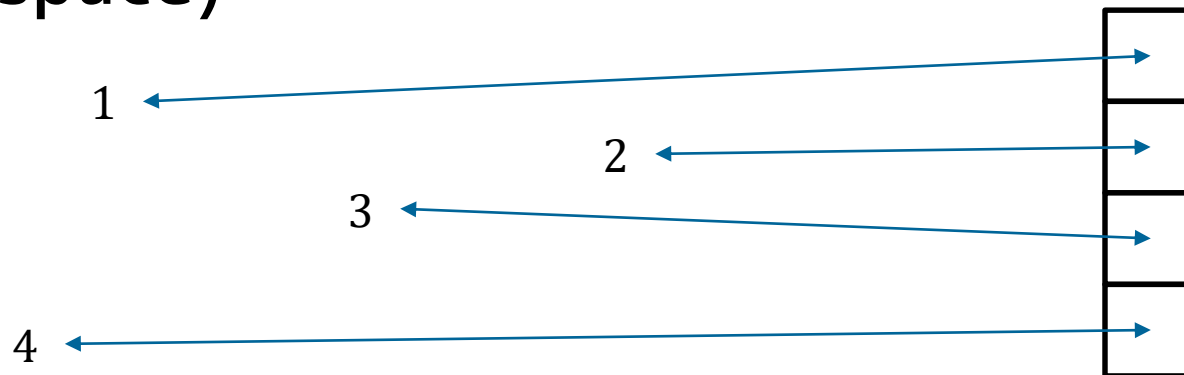

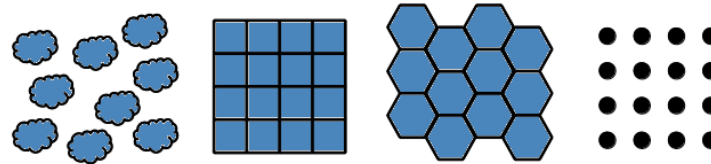

- States

- State-space

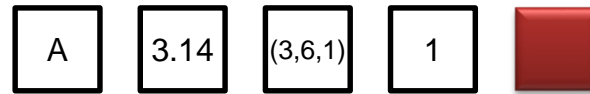

- Arrangement
(Cell-space)

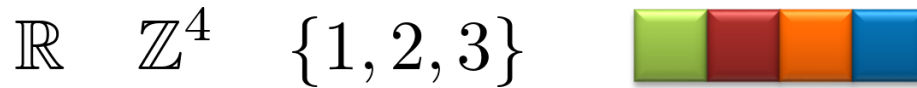

- Cells

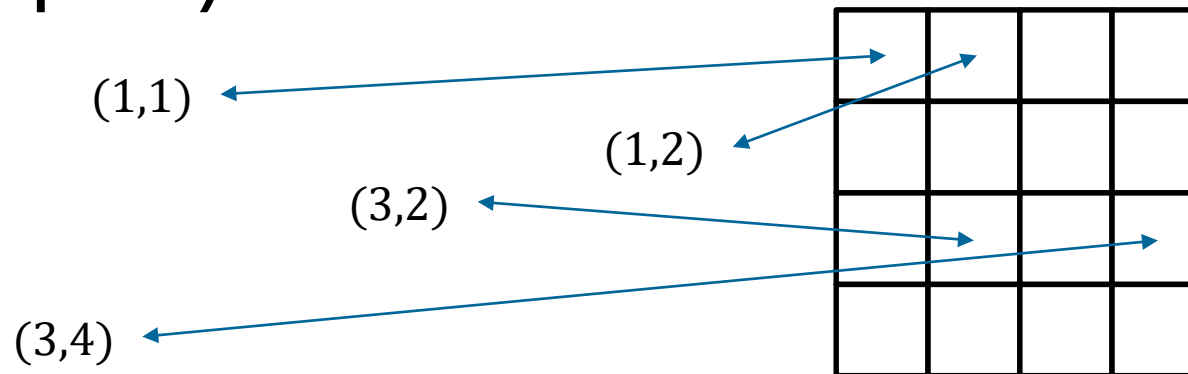

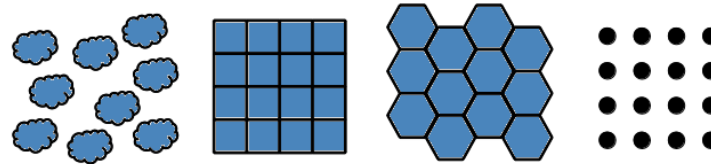

- States

- State-space

- Arrangement
(Cell-space)

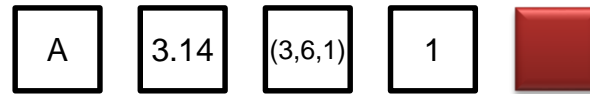

Components of a CA

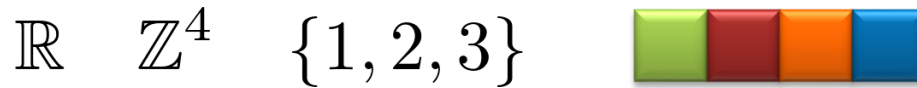

- Cells

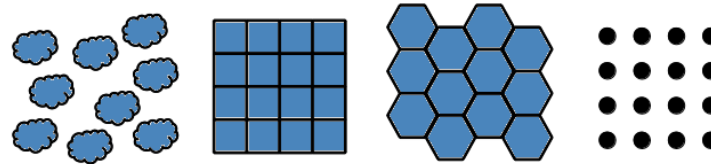

- States

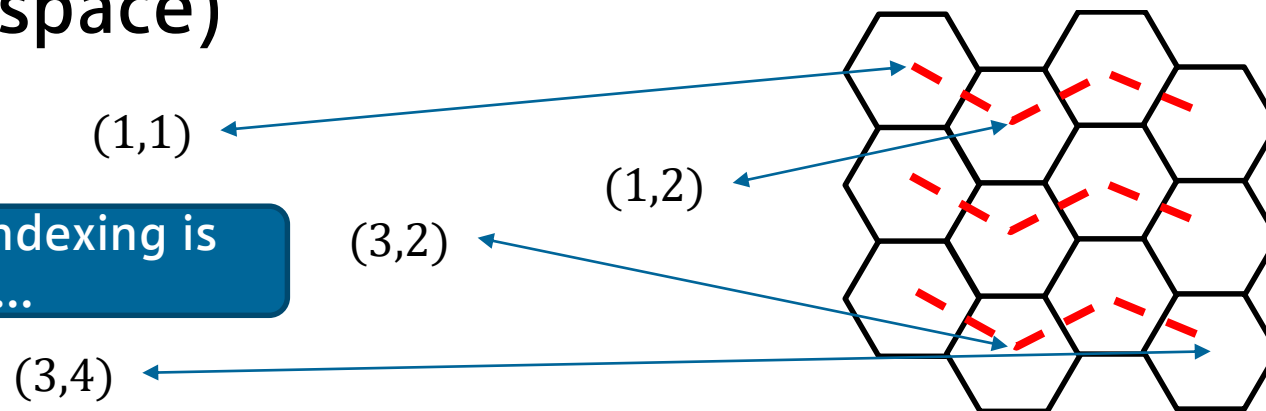

- State-space

- Arrangement
(Cell-space)

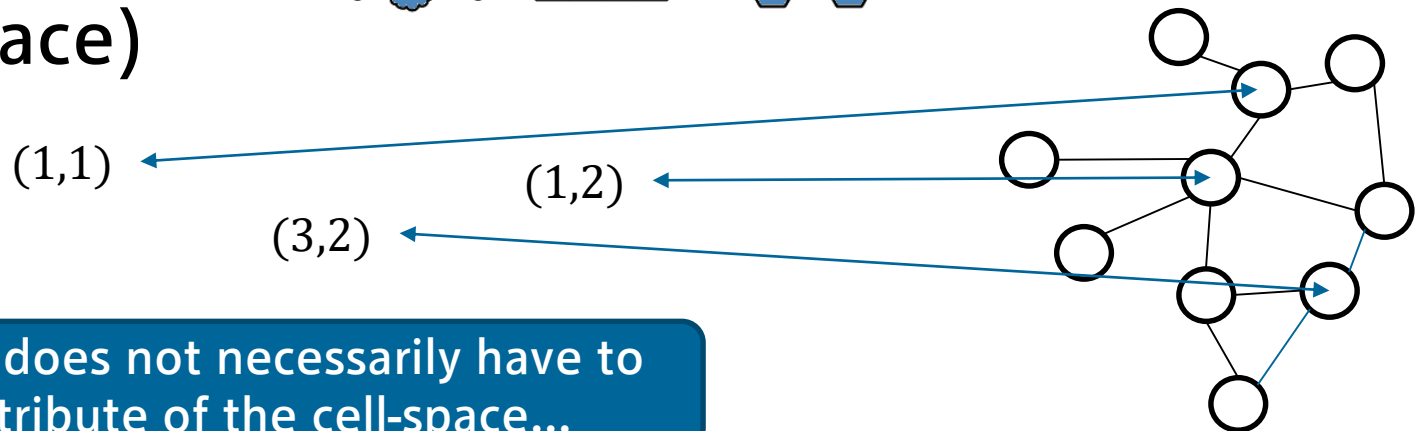

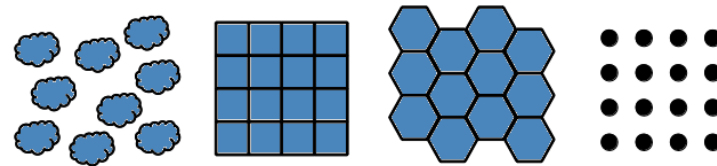

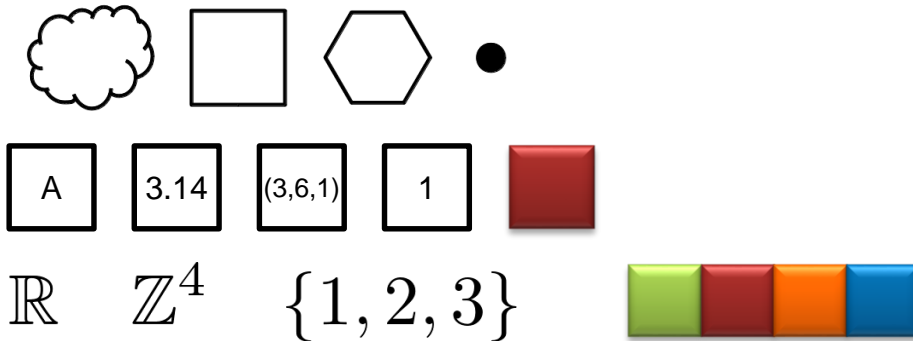

Sometimes indexing is not so trivial...

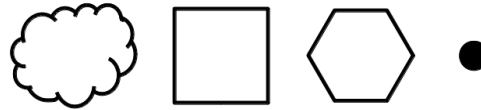

Components of a CA

- Cells
- States
- State-space
- Arrangement (Cell-space)

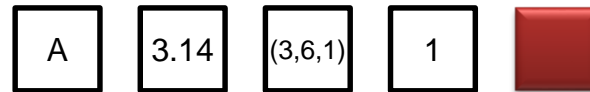

It often is, but does not necessarily have to be a natural attribute of the cell-space...

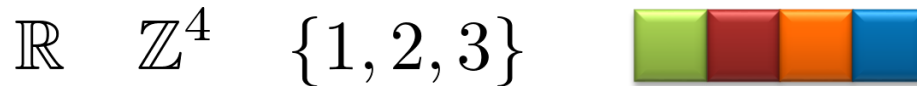

- Cells

- States

- State-space

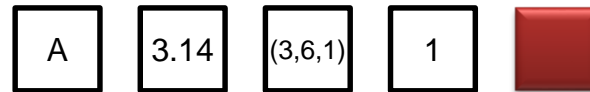

- Possible characteristics of the index set:
 - regular
 - finite or infinite
 - connected
 - multi-dimensional
- Interpretation of the index set: discretisation of a space or spatial arrangement of entities

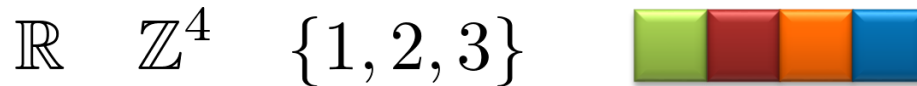

- Cells

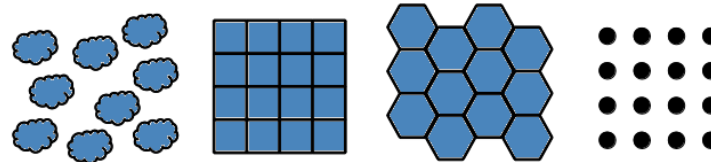

- States

- State-space

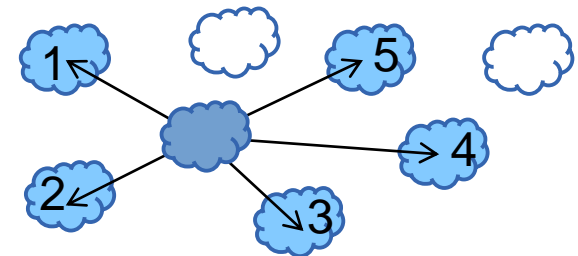

- Arrangement
(Cell-space)

- Neighbourhood

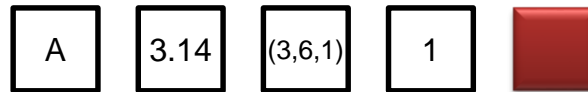

The neighborhood of a cell z is an ordered set of n other cells (z_1, \dots, z_n) .

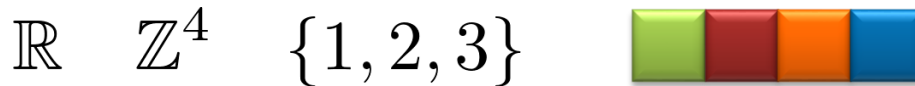

- Cells

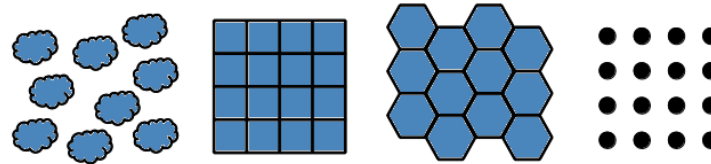

- States

- State-space

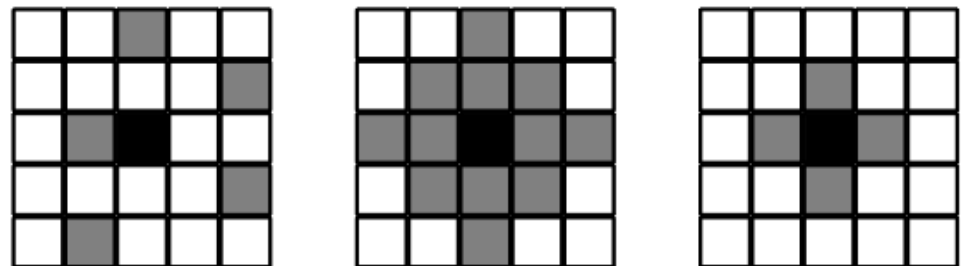

- Arrangement
(Cell-space)

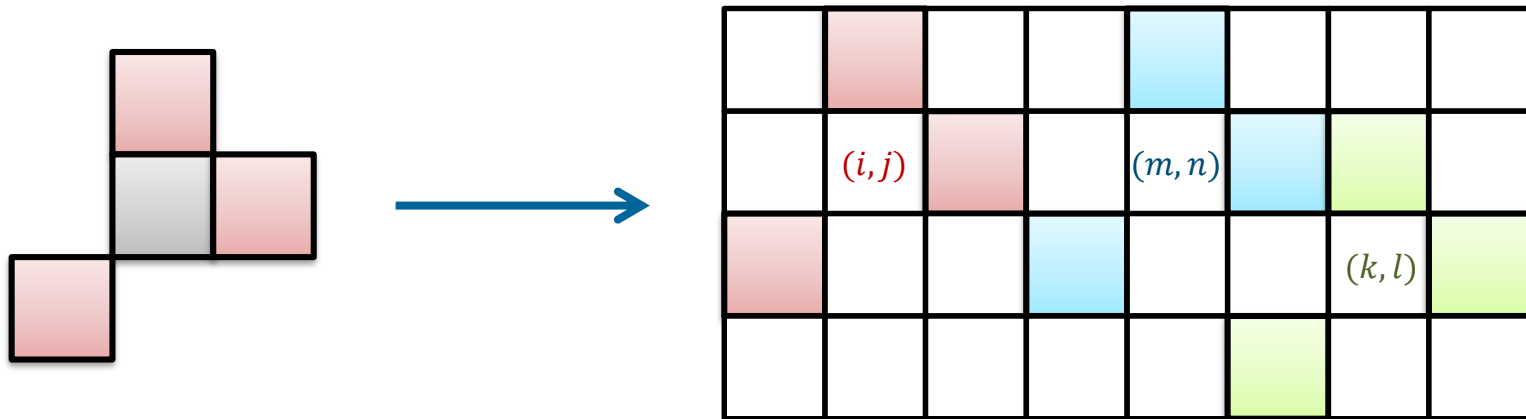

- Neighbourhood

Some examples:

- The neighbourhood mapping is relative to the cell's position (= index)

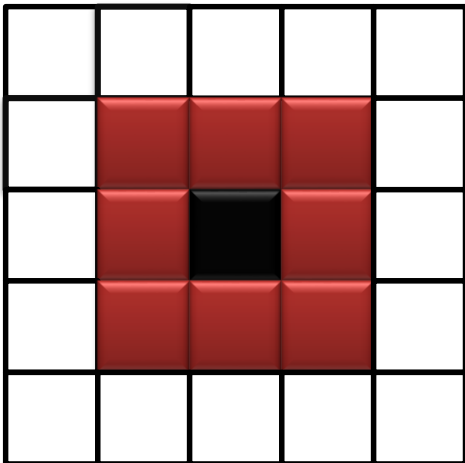

- Calculation of neighbouring cells by stencil:
Index translations yield the positions (index)
of n neighboring cells: $\vec{i} \mapsto (\vec{i} + \vec{t}_1, \dots, \vec{i} + \vec{t}_n)$

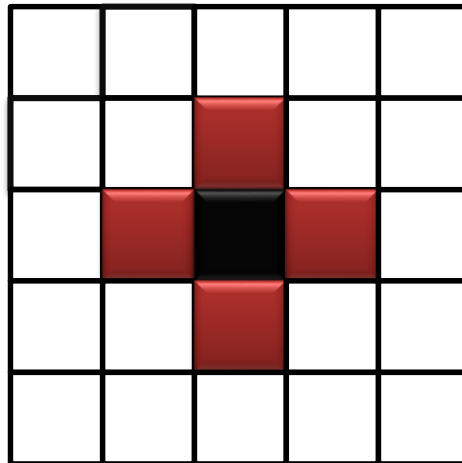

- Possible characteristics of neighbourhoods:
 - **local:** the neighbourhood consists of cells of neighboring points on the grid
 - **symmetric:** the neighborhood of cell A contains cell B if and only if the neighborhood of cell B contains cell A
-

- Classic, popular neighborhoods

Moore
neighborhood

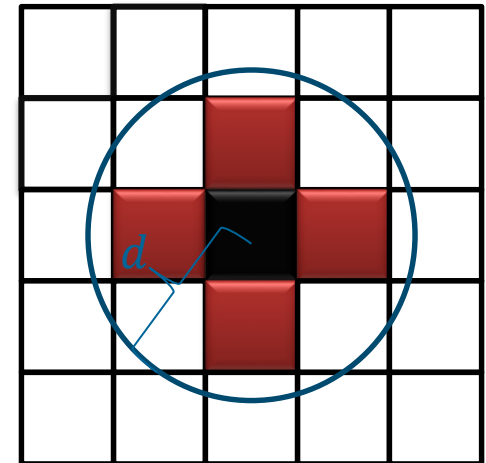

Von-Neumann
neighborhood

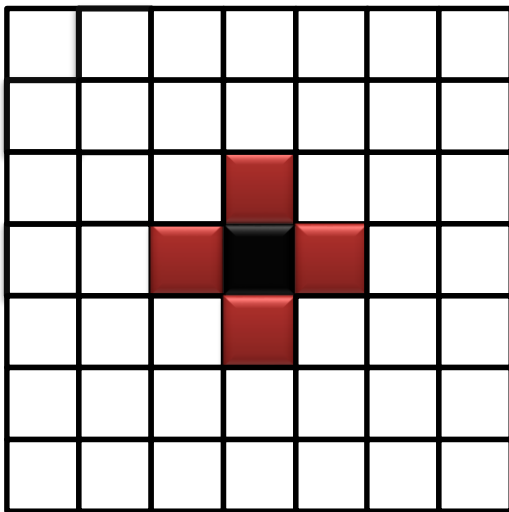

Neighbourhood by distance:

$$\vec{i} \rightarrow \{\vec{j} : |\vec{i} - \vec{j}| < d\}$$

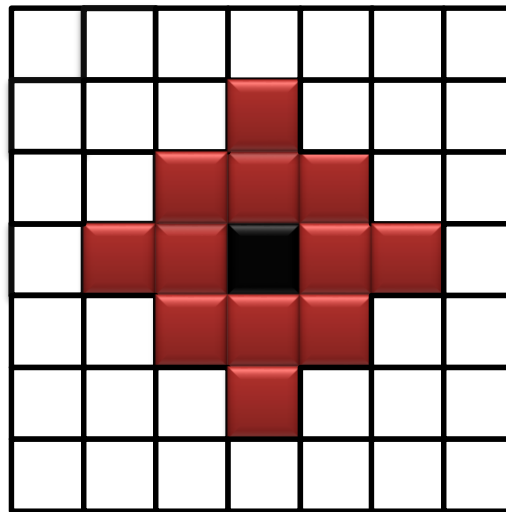

- Von Neumann/Moore Neighbourhood of higher order

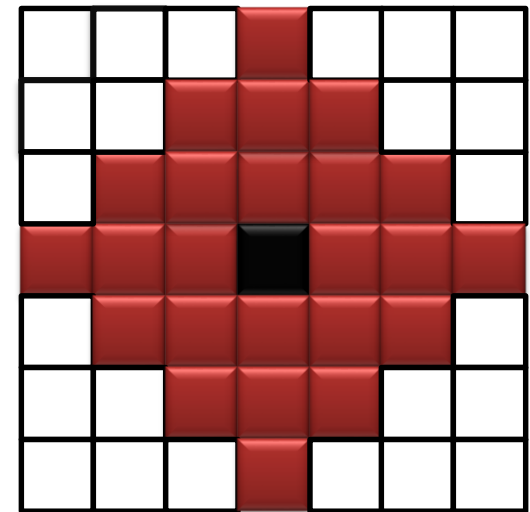

Von-Neumann
neighborhood
1st order

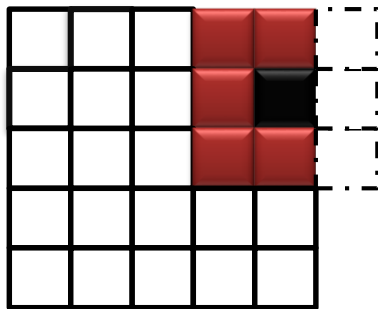

Von-Neumann
neighborhood
2nd order

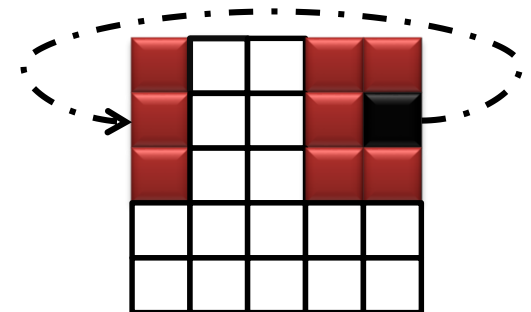

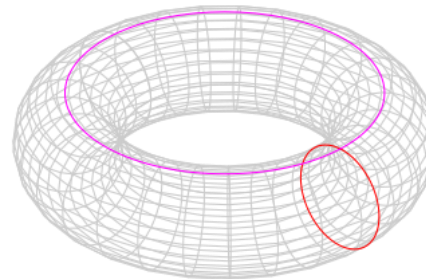

Von-Neumann
neighborhood
3rd order

- The index set is limited \rightarrow either incomplete neighborhoods for cells near the borders
 $(z_1, z_2, \emptyset, z_4, \dots, z_n) \dots$

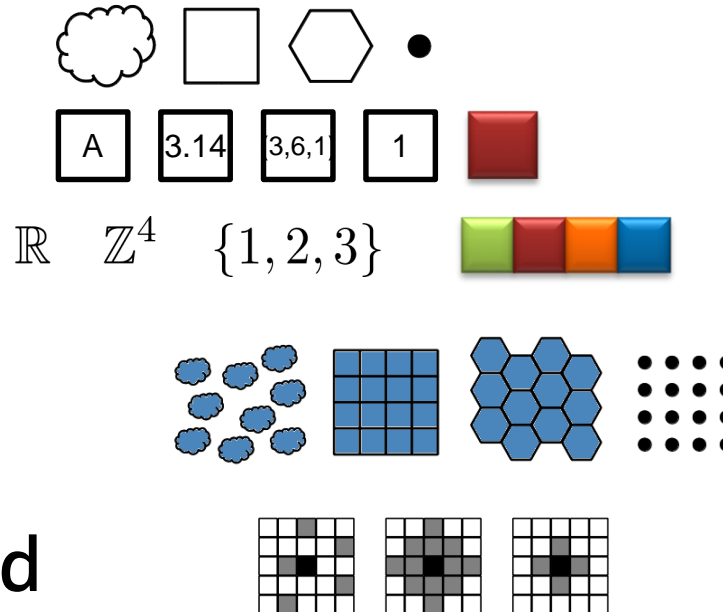

...or other compensation ideas.

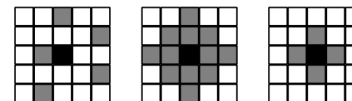

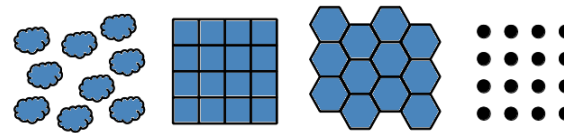

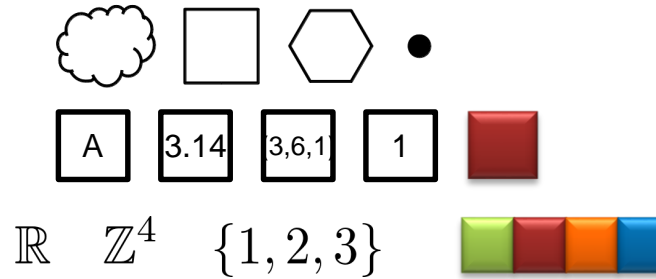

Periodic Boundary Conditions (Torus)

- Cells
- States
- State-space
- Arrangement (Cell-space)
- Neighbourhood
- Update Rule

Some rule, that simultaneously updates all states of all cells of the CA.
Maps all states of a cell's neighbourhood to a new state for the cell.

- Cells
- States
- State-space
- Arrangement (Cell-space)
- Neighbourhood
- Update Rule

$$f(s, s_1, \dots, s_n) = s_{new}$$

Stochastic CAs
have stochastic
updates!

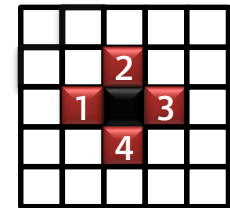

state of
the cell

state of the
(ordered) neighbors

new state of
the cell

Neighbourhood = Von Neumann

$$f(s, s_1, s_2, s_3, s_4) = \sum s \pmod{4}$$

New state of the CA

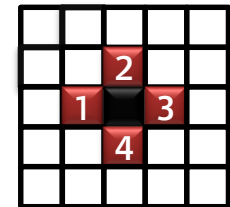

1	2	1	0	2	1	1
2	3	1	2	3	1	1
0	2	1	2	0	2	1
3	2	1	1	1	5	1
0	1	2	0	2	2	0
2	0	1	1	1	3	1
2	2	0	2	3	1	2

A blank 7x7 grid of squares, intended for drawing a 7-sided polygon.

■ Example:

Neighbourhood = Von Neumann

$$f(s, s_1, s_2, s_3, s_4) = \sum s \pmod{4}$$

Old state of the CA

1	2	1	0	2	1	1
2	3	1	2	3	1	1
0	2	1	2	0	2	1
3	2	1	1	1	5	1
0	1	2	0	2	2	0
2	0	1	1	1	3	1
2	2	0	2	3	1	2

$$\begin{aligned} f(s, s_1, s_2, s_3, s_4) &= \\ &= 1 + 1 + 2 + 1 + 0 \pmod{4} = \\ &= 5 \pmod{4} = 1 \end{aligned}$$

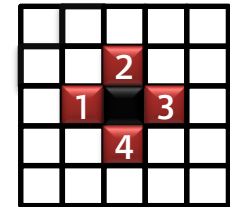

New state of the CA

				1		

■ Example:

Neighbourhood = Von Neumann

$$f(s, s_1, s_2, s_3, s_4) = \sum s \pmod{4}$$

Old state of the CA

1	2	1	0	2	1	1
2	3	1	2	3	1	1
0	2	1	2	0	2	1
3	2	1	1	1	5	1
0	1	2	0	2	2	0
2	0	1	1	1	3	1
2	2	0	2	3	1	2

$$\begin{aligned} f(s, s_1, s_2, s_3, s_4) &= \\ &= 1 + 1 + 2 + 3 + 3 \pmod{4} = \\ &= 10 \pmod{4} = 2 \end{aligned}$$

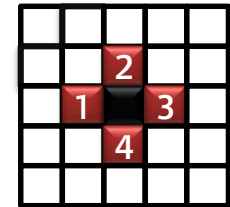

New state of the CA

			1			
					2	

■ Example:

Neighbourhood = Von Neumann

$$f(s, s_1, s_2, s_3, s_4) = \sum s \pmod{4}$$

Old state of the CA

1	2	1	0	2	1	1
2	3	1	2	3	1	1
0	2	1	2	0	2	1
3	2	1	1	1	5	1
0	1	2	0	2	2	0
2	0	1	1	1	3	1
2	2	0	2	3	1	2

$$\begin{aligned} f(s, s_1, s_2, \emptyset, s_4) &= \\ &= 1 + 1 + 1 + 1 \pmod{4} = \\ &= 4 \pmod{4} = 0 \end{aligned}$$

New state of the CA

						0
			1			
					2	

The update function needs to be capable to deal with incomplete neighbourhoods as well

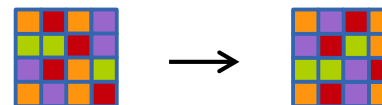

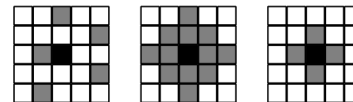

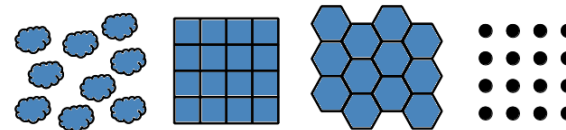

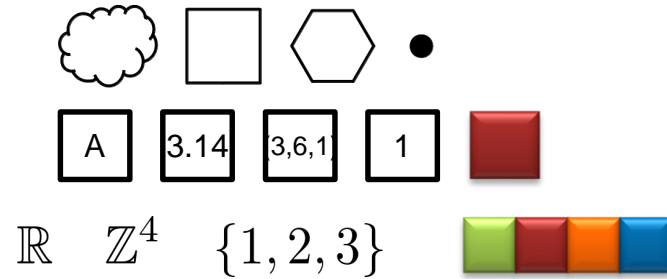

- Updates happen for all cells simultaneously.

Why?

- Neighborhoods are all computed from the same system state
- Update order of cells is irrelevant

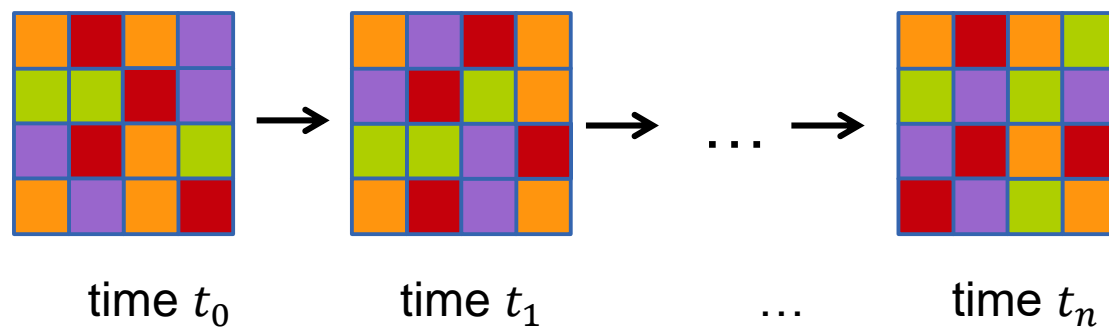

- Cells
- States
- State-space
- Arrangement (Cell-space)
- Neighbourhood
- Update Rule
- Iterations

Iteratively apply the update rule on the complete CA finally leads to a simulation model

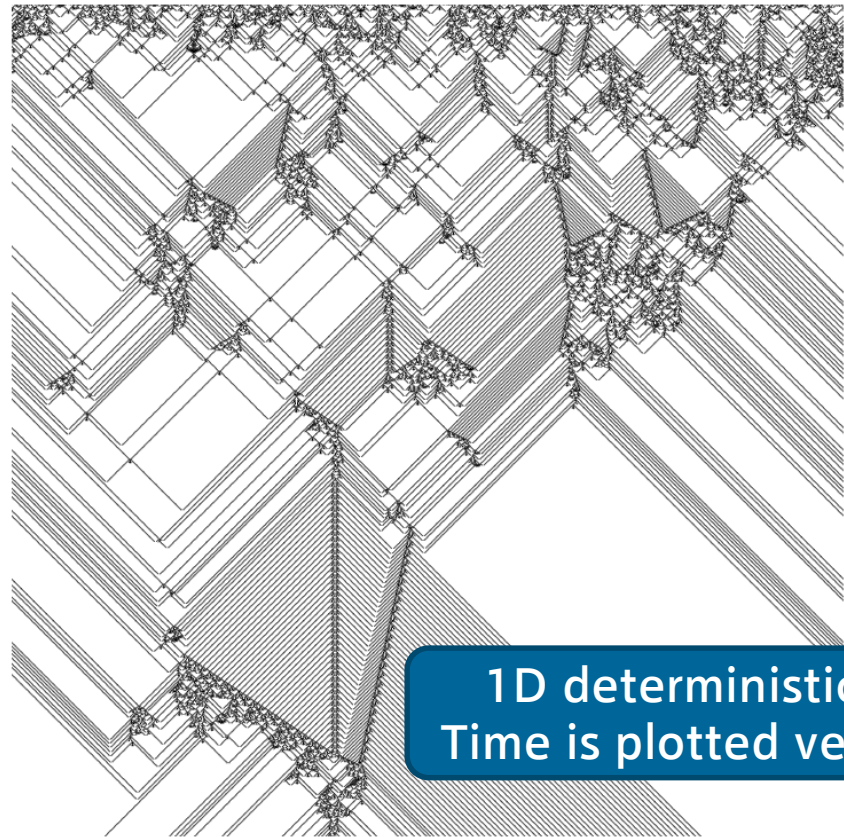

- Define discrete, equidistant time points (all time steps between time points are of the same length): t_0, t_1, \dots, t_n
 - Every update of states brings the model to the next time point
- Cellular Automaton (CA)
-

- Tasks for one iterations
 - Compute the neighbors of all cells
 - Determine states of all cells, and states of all neighbours of all cells
 - Compute state updates for all cells and store them
 - Apply the updated states for all cells

Cellular Automata are microscopic simulation models that are capable of producing almost arbitrarily complex, up to chaotic, behaviour.

They are, hence, not only a very powerful, but also a very dangerous modelling approach with respect to validity.

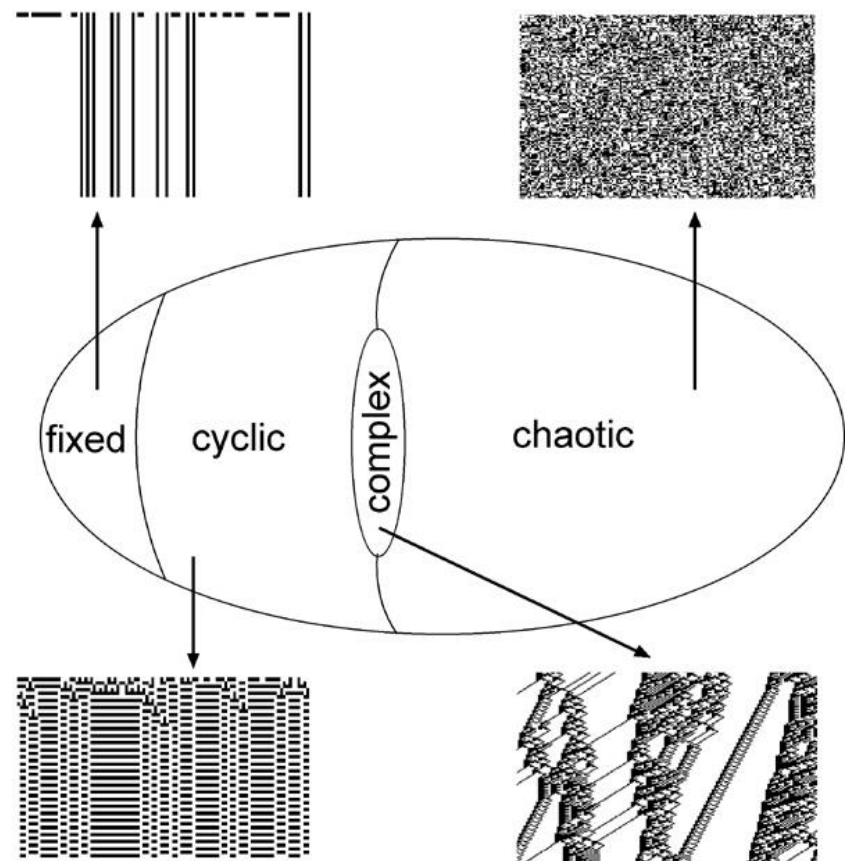

1D deterministic CA!
Time is plotted vertically

Cellular Automata are microscopic simulation models that are capable of producing almost arbitrarily complex, up to chaotic, behaviour.

Stephen Wolfram
(A New Kind of Science, 2002)
stated that CAs may have one
of the four types of
behaviour:

fixed, cyclic, complex, chaotic

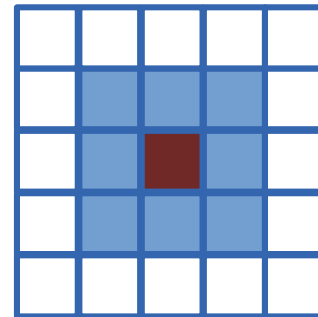

Chris Langton developed
the schematic to the right.

Example:

CONWAY'S GAME OF LIFE

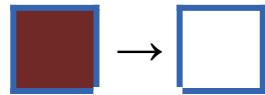

- Cells on a 2-dimensional, rectangular or infinite lattice: $I = (1, 2, \dots, a) \times (1, 2, \dots, b)$ or on $I = \mathbb{Z}^2$.
- Set of states: $\mathbb{S} = (\text{alive}, \text{dead})$
- Moore neighborhood

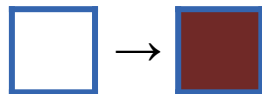

Index translations:

$$\left(\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \end{pmatrix}, \begin{pmatrix} 0 \\ -1 \end{pmatrix}, \begin{pmatrix} 1 \\ -1 \end{pmatrix} \right)$$

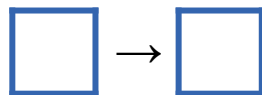

- Update rules:

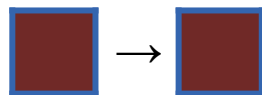

- An alive cell with fewer than two or more than three alive neighbors dies (“under-population” or “overcrowding”)

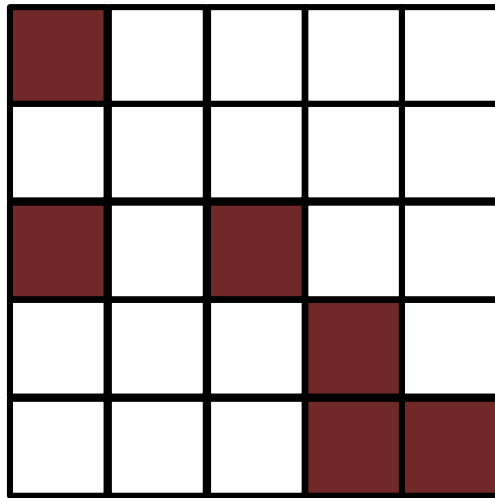

- A dead cell with exactly three alive neighbors becomes alive (“reproduction”)

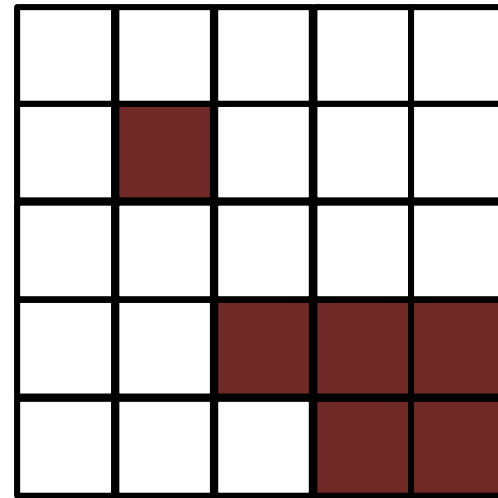

- Cells keep their state in any other case

Conway's Game of Life

time $t=0$

time $t=1$

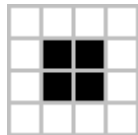

- Designed by John Horton Conway, 1970
- Why “Game of Life”?
 - Teaching purposes
 - Academic competitions
 - Fundamental/methodological research
 - Game → figures

Probably worst example for a Cellular Automata simulation model,...

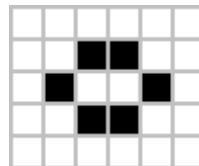

...but probably the best example to show the concepts of CAs.

Pattern analysis of the Game of Life became its own science (although its applicability can be doubted).

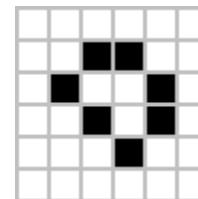

Static figures

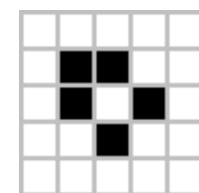

Block

Beehive

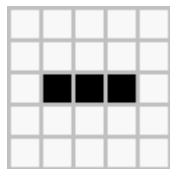

Loaf

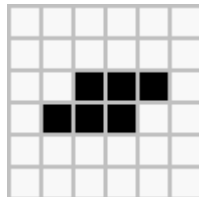

Boat

Pattern analysis of the Game of Life became its own science (although its applicability can be doubted).

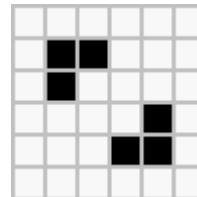

Oscillators

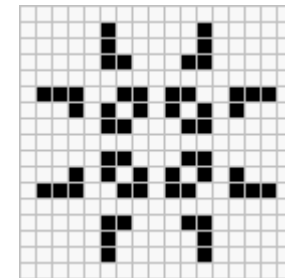

Blinker (period 2)

Toad (period 2)

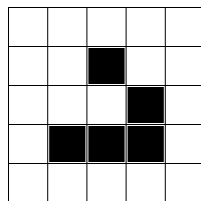

Beacon (period 2)

Pulsar (period 3)

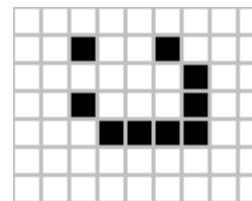

Pattern analysis of the Game of Life became its own science (although its applicability can be doubted).

Gliders (moving objects)

Glider

Lightweight spaceship (LWSS)

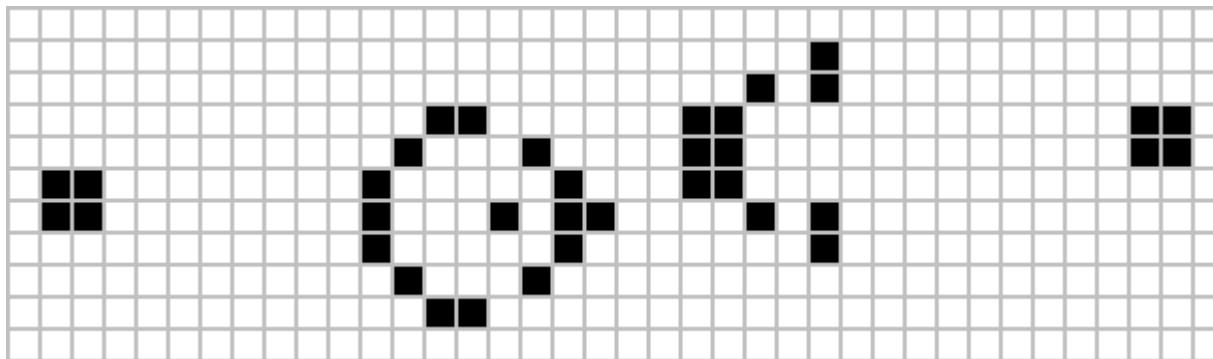

Pattern analysis of the Game of Life became its own science (although its applicability can be doubted).

As it seemed as if any starting configuration of the GoL resulted in a static or oscillating end-configuration, Conway offered a price of 50\$ for a pattern that resulted in an infinitely growing population.

Pattern analysis of the Game of Life became its own science (although its applicability can be doubted).

Bill Gosper's answer:

Gosper Glider Gun

Example

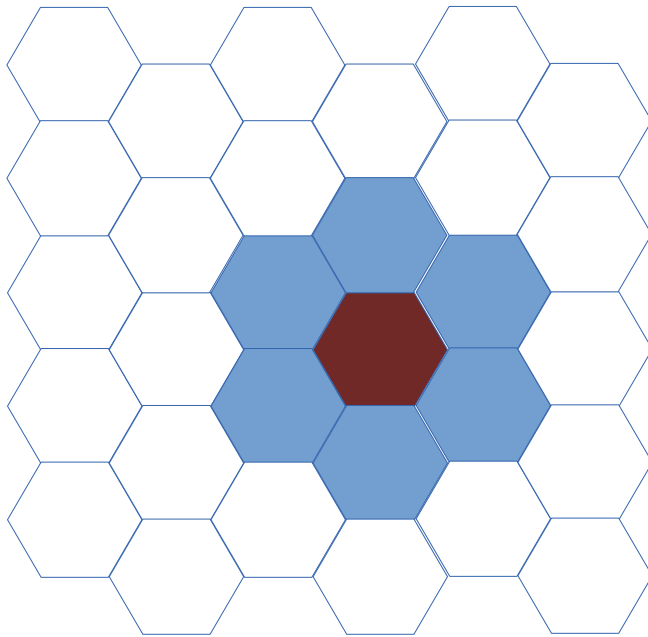

LATTICE GAS CELLULAR AUTOMATA (LGCA)

- Lattice Gas Cellular Automata (LGCA)
 - Extension of the CA concept
 - Intention: Simulate fluids and gases
 - Invented by Hardy, Pomeau and de Pazzis (HPP automaton on square lattice), 1973
 - Improved by Frisch, Hasslacher and Pomeau (FHP automaton on hexagonal grid), 1986
-

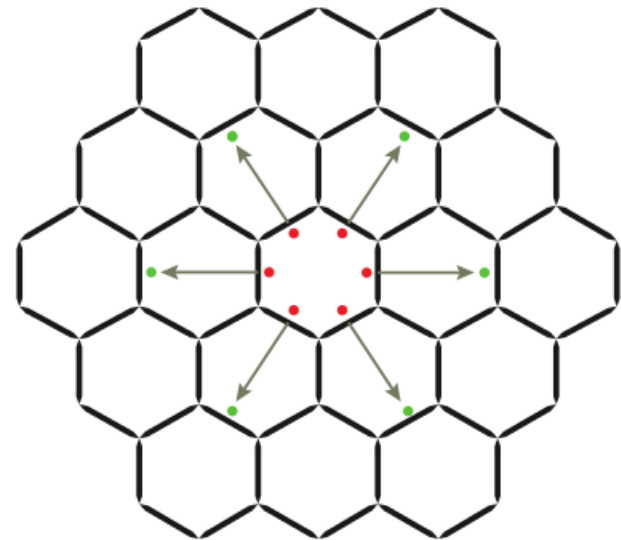

- **Ideas**
 - Cells do not have states but instead can contain particles
 - A particle can only proceed to a cell in the neighborhood
 - Instead of state updates, particles move to other cells
 - Particles represent the fluid or the gas
-

- **HPP**
 - square grid, Von-Neumann neighborhood, max. 4 particles per cell so that max. 1 particle goes to each neighbor
 - several issues when it comes to real interpretations (comparison with real fluids, validation)
-

- **FHP**
 - hexagonal grid
 - neighborhood = surrounding cells
 - max. 6 particles per cell, each going into a different direction → consistent definition
 - Corresponds to the Navier-Stokes-Equations → valid representation of fluid dynamics
-

neighbourhood

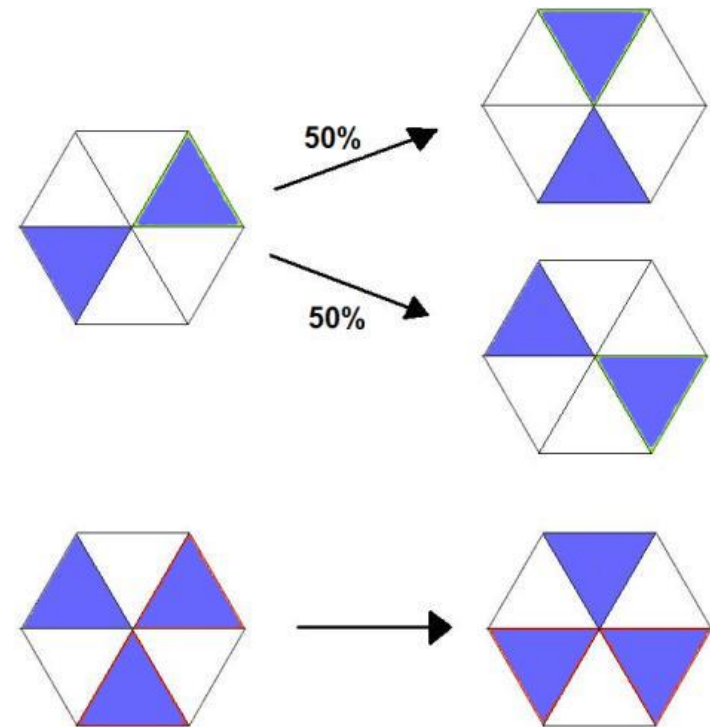

particles and directions

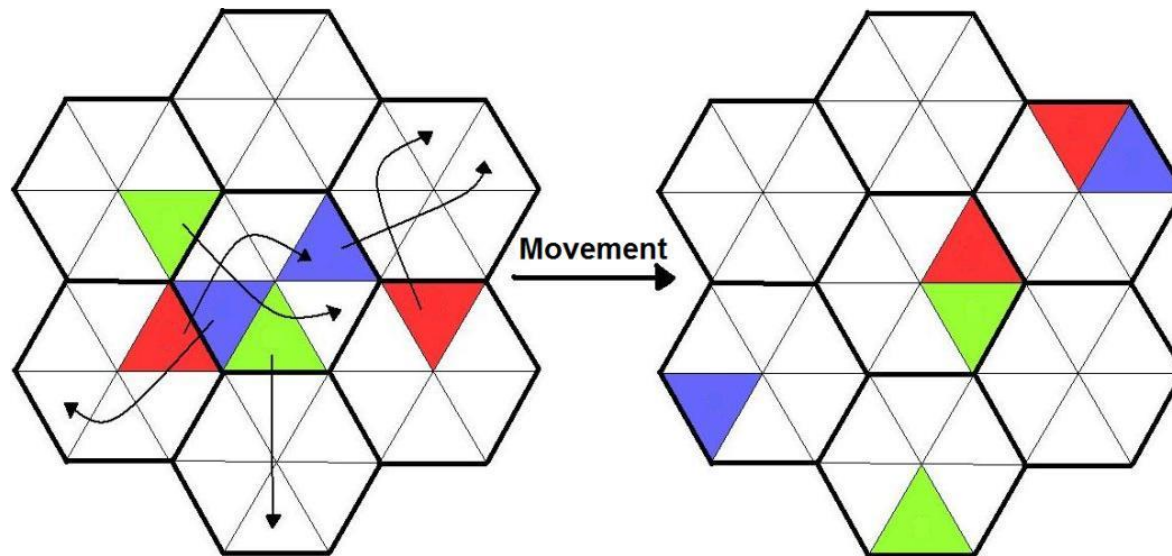

- Particle movements consist of two phases
 - Rotation of cells for special configurations
 - Movements of particles into their direction
 - Developed by Wolf-Gladrow (2000)
 - Different variations (FHP-I, FHP-II, FHP-III)
-

- Rotations

- In the most simple case of FHP-I only for two situations
- Provide a randomness

- Movements into designated directions

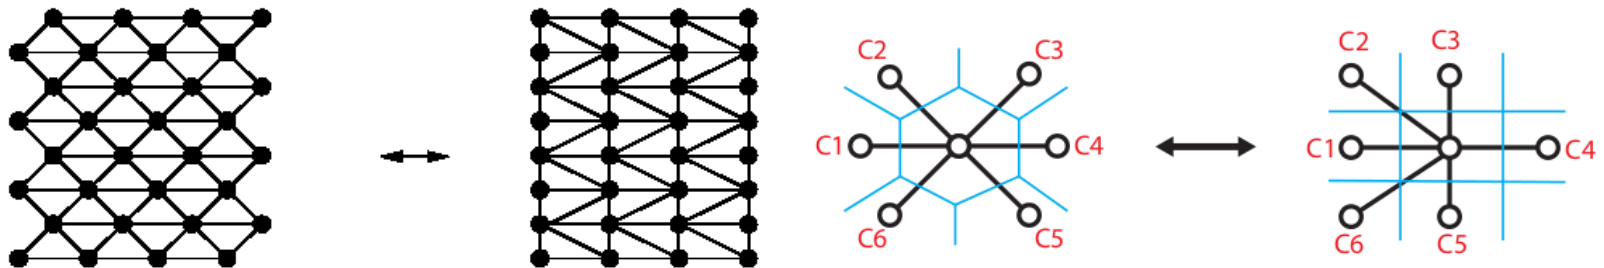

- **Simulations & Visualizations**
 - **HPP**
 - http://en.wikipedia.org/wiki/File:Gas_velocity.gif
 - **FHP**
 - <http://www.youtube.com/watch?v=HluQpDFOceg>
 - <http://www.youtube.com/watch?v=00W6H7BGZ94>
-

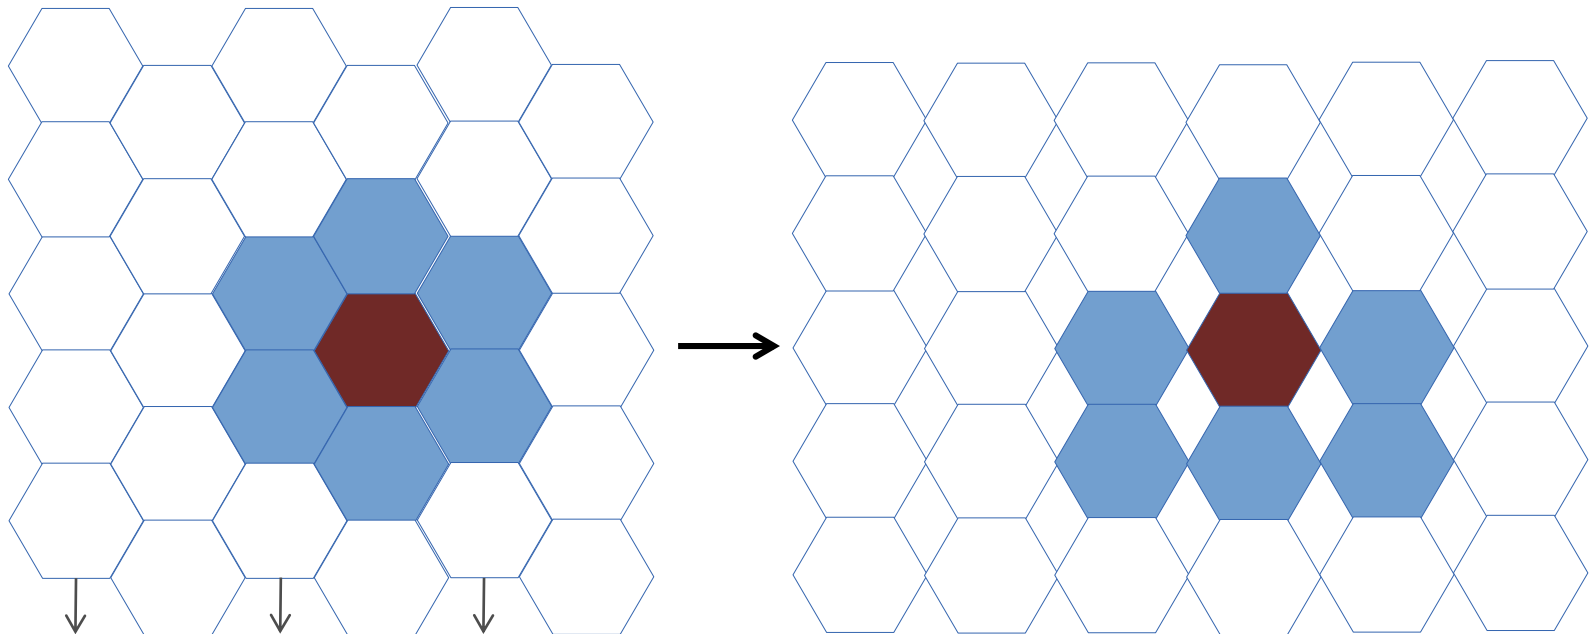

Remark: Implementation of a hexagonal grid

- **Implementation**

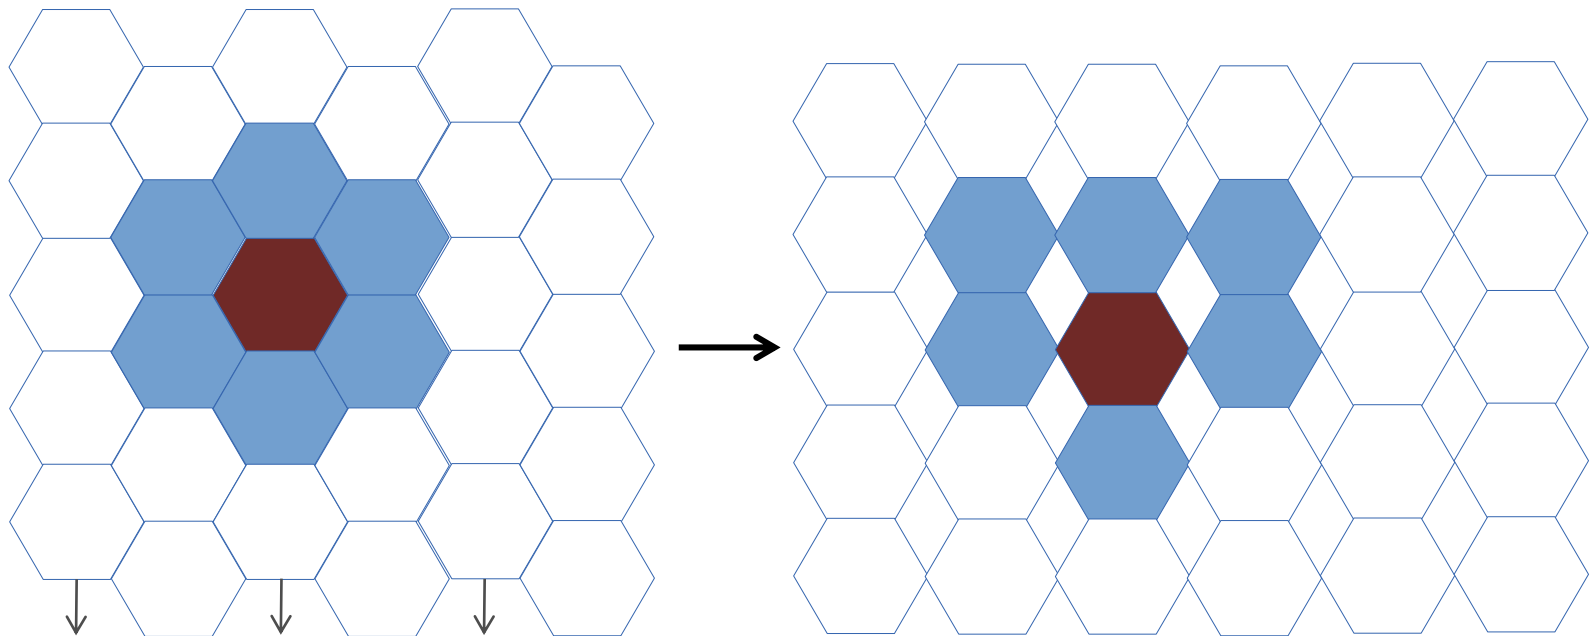

- hexagonally arranged grid \rightarrow assign to a square lattice
- conditional neighborhoods

Remark: Implementation of a hexagonal grid

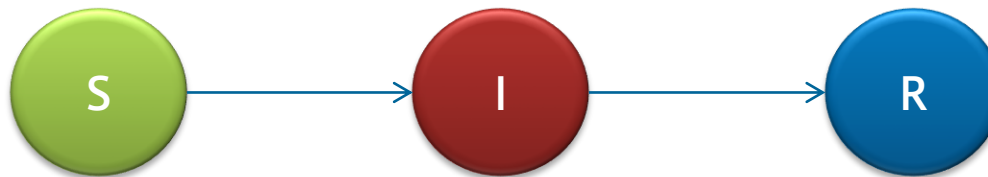

Remark: Implementation of a hexagonal grid

Example

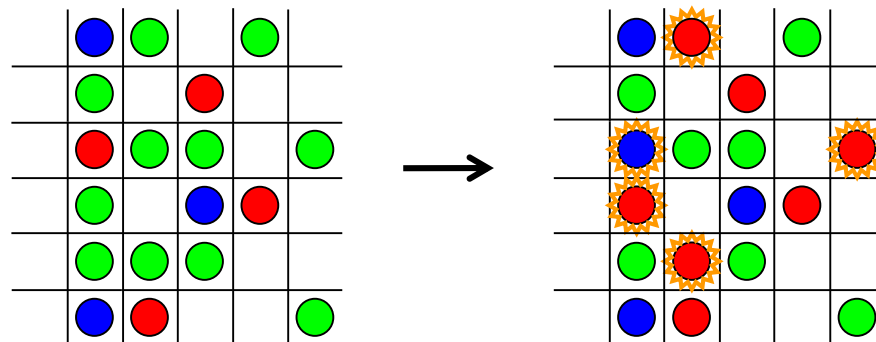

EPIDEMIC SIMULATION WITH CA AND LGCA

- Simulate the spread of an epidemics
- Susceptible (S) people become infected by infectious (I) and become resistant/recovered (R) after some time.
- Resistant persons cannot be infected again.

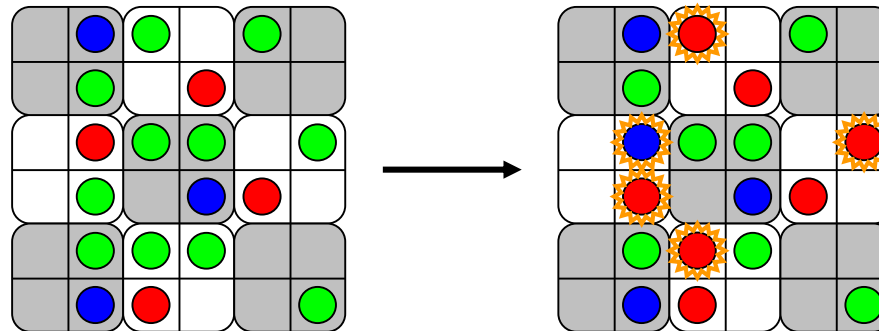

CA Implementation of SIR epidemics:

- Every cell in a rectangular (hexagonal..) lattice represents a person/group of persons/household/...
- Infectious cells recover after some time (with some probability).
- Infectious cells may spread the disease to their neighbours (e.g. Moore neighbourhood)

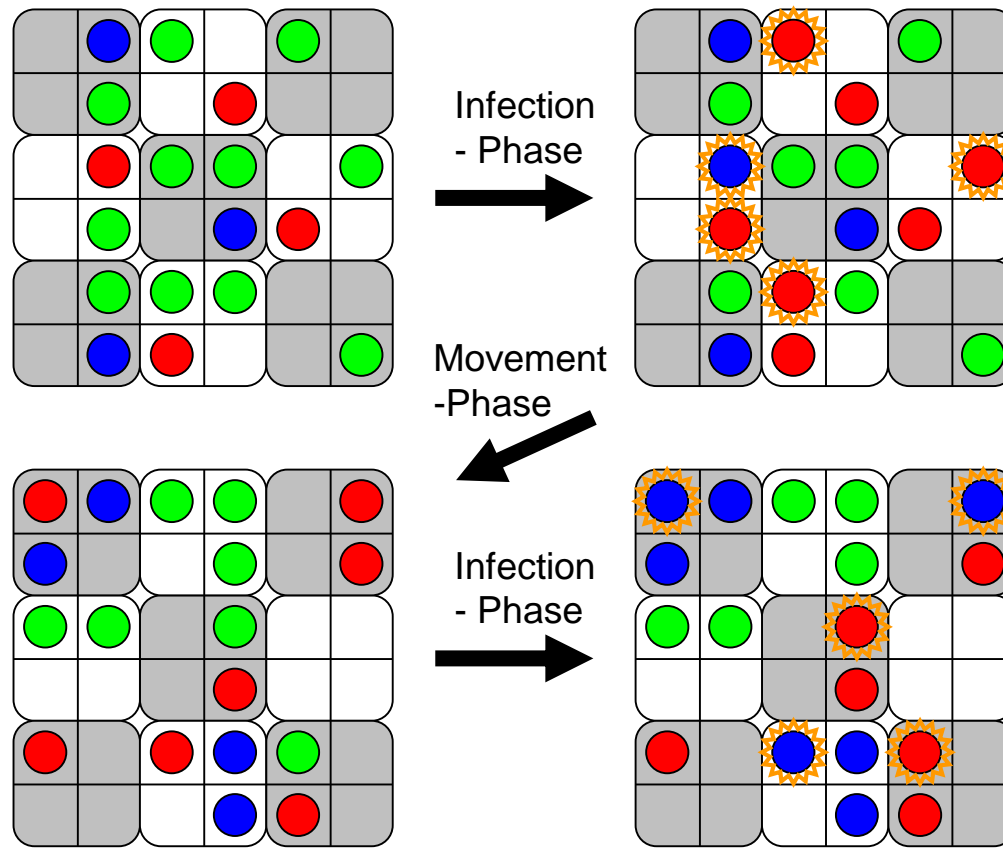

LGCA Implementation of SIR epidemics:

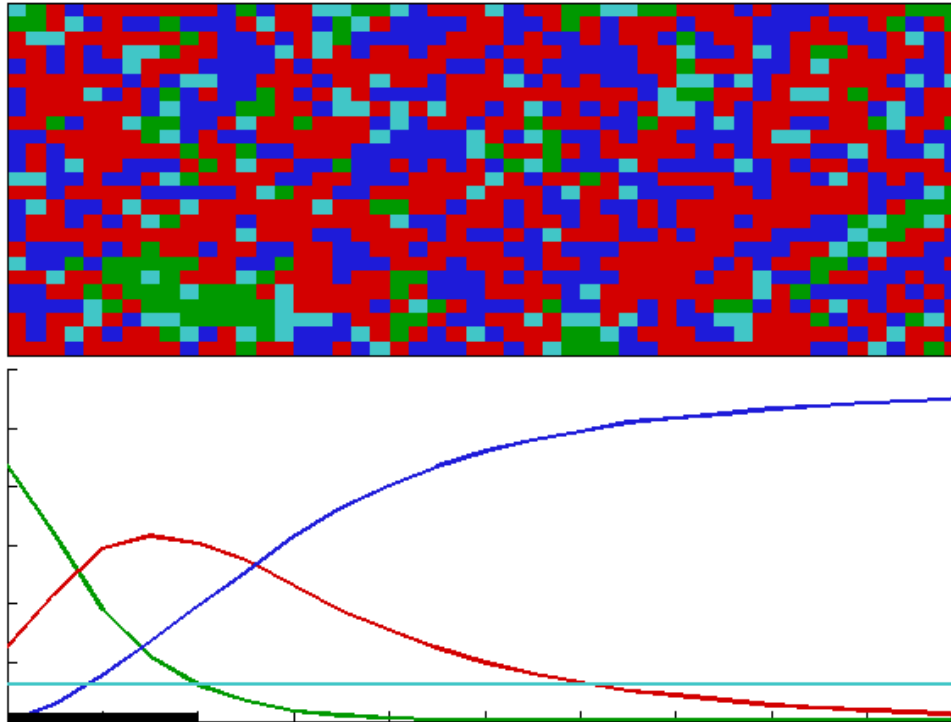

- Every cell in a rectangular (hexagonal..) lattice contains a number of persons (e.g. 4)
- Infectious persons recover after some time (with some probability).
- Infectious persons may spread the disease to all other persons in the cell

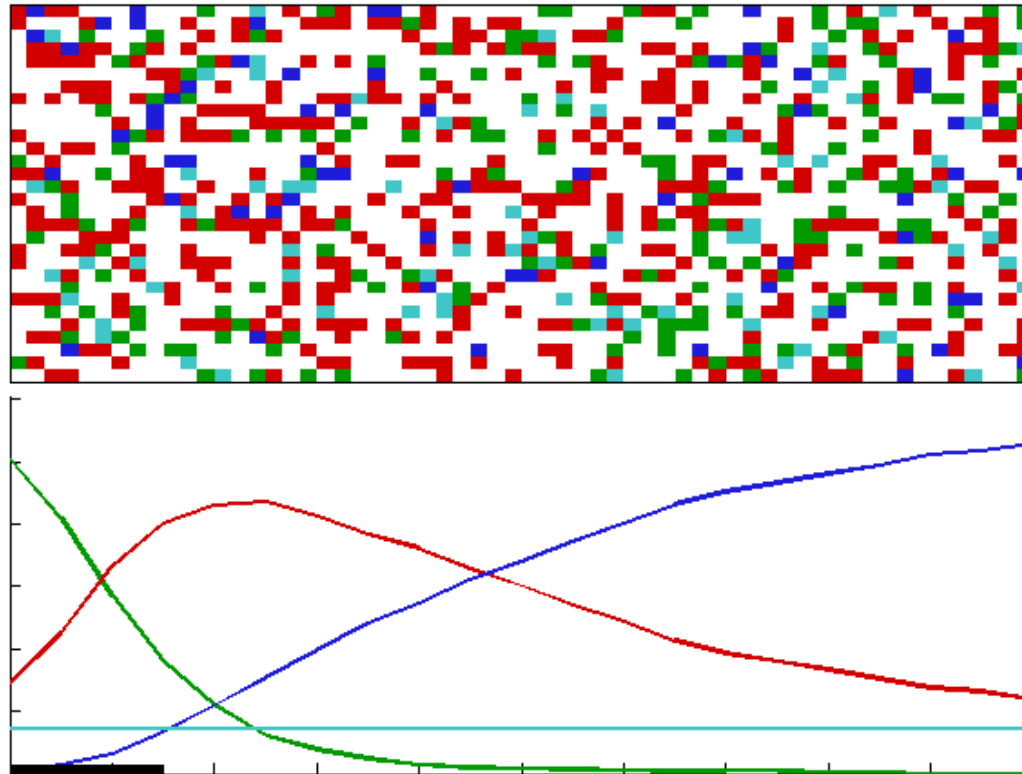

LGCA Implementation of SIR epidemics:

Epidemic simulation with CA

Epidemic simulation with HPP-LGCA

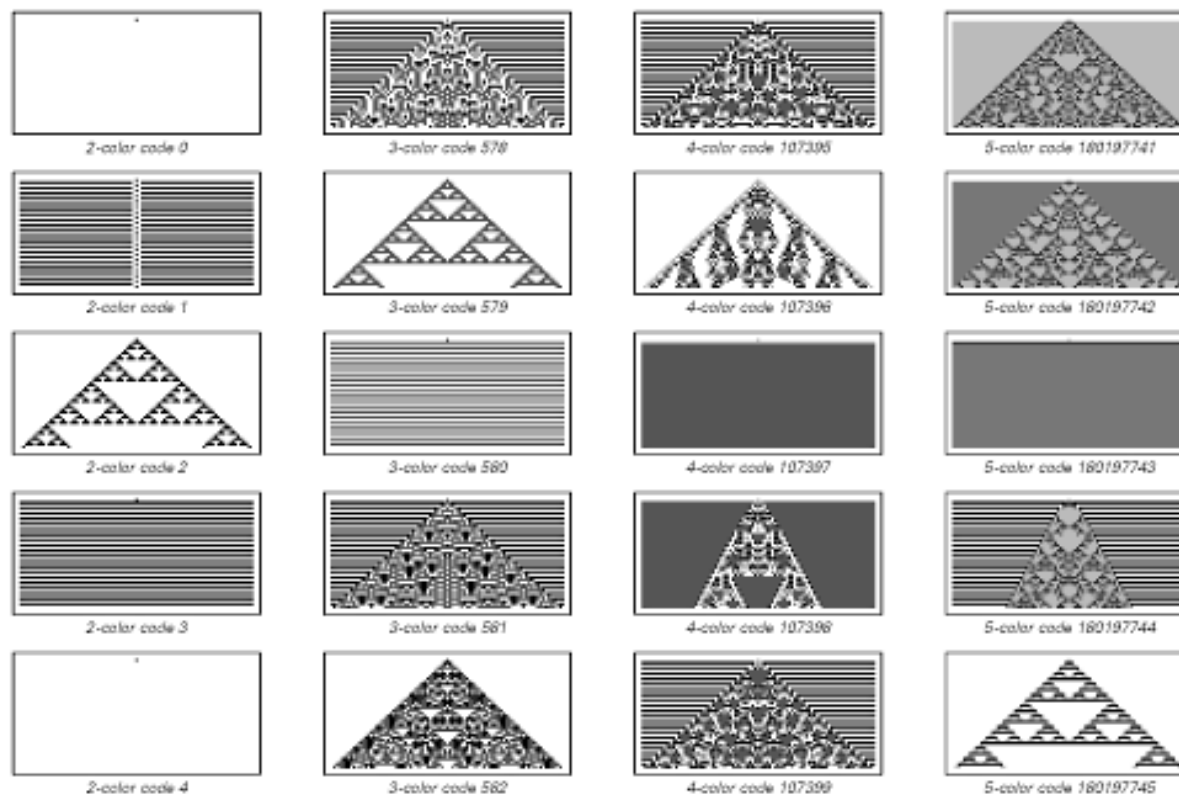

HISTORY OF CELLULAR AUTOMATA

- 1925: Ising Modell
 - ferromagnetism, discrete model
 - 1950: Von Neumann, Ulam
 - term “cellular automaton”
 - self reproductive, Von-Neumanns theory on logic automata
-

-
- 1950-1970: Zuse, u.a.
 - parallel algorithms
 - discrete processes (e.g. PDEs)
 - 1970s: Hardy, Pomeau, de Pazzis
 - Lattice Gas Cellular Automata
 - 1979: Conway's Game of Life
-

- 1980+: different applications
 - 2002: Wolfram
 - complete classifications of 1-dimensional cellular automata
-

Stephen Wolfram, „A new Kind of Science“

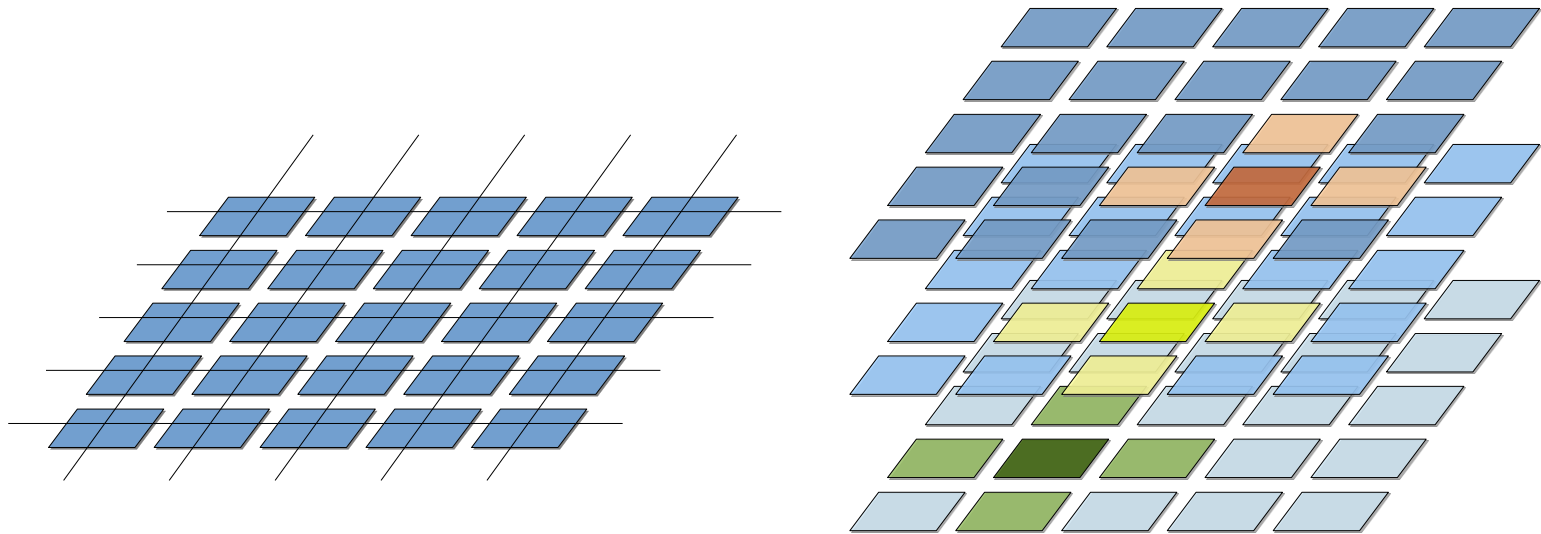

- a spatially extended decentralized system made up of a number of individual components [...] local interaction [...] depending on the states of its local neighbors [...] parallel processing [Ganguly]
 - regular grid of cells, each in one of a finite number of states [...] neighbourhood [...] new generation is created according to some fixed rule [Wikipedia]
-

- regular arrangements of single cells [...] each cell holds a finite number of discrete states [...] updated simultaneously [...] the rules for the evolution of a cell depend only on a local neighborhood [Gladrow]

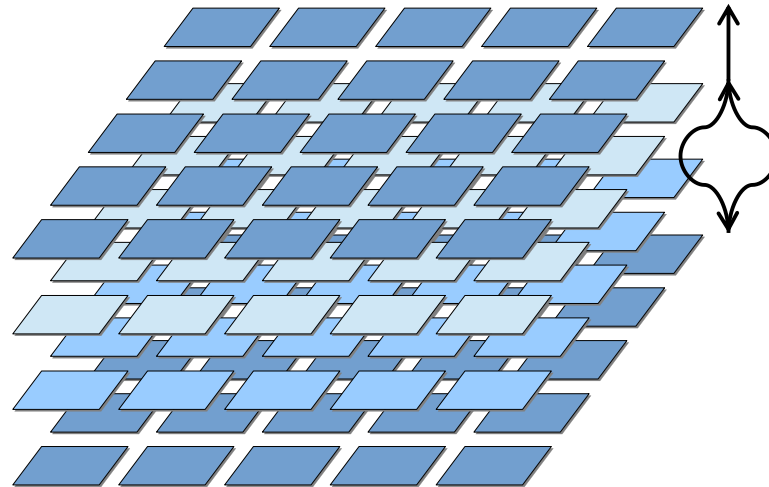

5. Conclusions

CONCLUSIONS

- Regular lattice, same kind of neighbourhoods

- Discrete time, equidistant time steps

- Spatial representation, locality
