Kevin Sturm The basics

# Python references

The basics

- · Good python book Python 3 (2017 edition) by Johannes Ernesti and Peter
- online documentation: https://docs.python.org/3.6/

The basics Historical facts

# Why python?

- developed in the nineties by Guido van Rossum in Amsterdam at Centrum voor Wiekunde en Informatica the name "python" comes from the comedy "Monty Python"
- python version 3.0 was released in December 2008
- one of the most popular programming languages
- designed for functional and object oriented programming
- programs that partially use python:
  - \* Google Mail
  - \* Google Maps
  - \* YouTube
  - \* Dropbox
  - \* reddit

  - \* Battlefield 2
  - \* BitTorrent

# What does python offer?

- Interactive
- Interpreted
- Modular
- Object-oriented
- Portable
- High level
- Extensible in C++ & C

# Why is python good for scientifc comput-

open source / free

ing?

- many libraries, e.g., scientific computing: numpy, scipy
- symbolic math: sympy
- plotting: matplotlib
- excellent PDE solver software:
- ngsolve, FEniCs, Firedrake, ...

# How to start python?

- Python can either be used interactively: simply type "python3" or "ipython3" (to start IPvthon) into the shell
- we can also execute python code written in a file "file.py" by typing "python3 file.py" into the shell

Let's start with a hello world example:

# Listing 1: hello\_world.py

```
This is our first program """
```

```
print("Hello world!")
```

# Float

#### declaration of floats >>> v = 987 27

333 Y 987.27

division

>>> y = 2.27 >>> x/y

434.92070484581495 floor division

# >>> x//v

# addition and subtraction

>>> v = 987 27 >>> v = 2.0>>> x+v 989.27

>>> x-v 985.27

#### powers >>> x\*\*2

>>> vas2 962294095.766583

>>> x\*\*0.5 # square root

### multiplication

>>> x\*v 1974.54 >>> x\*-y

The basics The basics Complex number imaginary unit in python is j floor division recall (a + ib) \* (c + id) := ac - db + i(bc + ad) >>> x//v 493 >>> z = 1.0 + 5j # complex number with real 1 and imag 5 declaration of integer >>> z.conjugate() # conjugate complex number conversion of float to integer >>> x = 1.4 >>> z = complex(1,5) # equivalent to 1+5; >>> v = int(x) >>> z = int(10.0)>>> v >>> z.imag # return imaginary part >>> x + 3 >>> z.real # return real part multiplication and division remember: float + int = float 1.666666666666667 400 (B) (E) (E) (B) (000 (B) (B) (E) (E) E 990

# The basics

Strings

The basics

conversion of float and integer to string

Complex number (continued)

#### multiplication of complex numbers

```
>>> z1 = 1 + 4 j
>>> z2 = 2 - 41
```

(18+41)

Integers

calculator >>> 1+3 >>> 3-10

>>> 30\*3

>>> x = 987 >>> x

90

987

10

>>> 2

>>> y = 2

>>> x/y 493.5 >>> 5/3

#### 

#### declaration of strings >>> a = "hello" # assign hello

>>> a

#### addition of strings >>> a+a

'hellohello' >>> 81 >>> a+" cool" 1987 271 'hello cool' >>> n = 10

#### referencing letters

>>> fourth = a[3] # 4th letter >>> fourth

# >>> last = a[-1] # last letter

>>> last

>>> x = 987.27

>>> s1 = str(x)

>>> s2 = str(n)

>>> 82

```
Strings (continued)
                                                                                         Lists
    lower and upper case
                                         accessing letters
                                                                                                                                       other ways to generate lists
    >>> a = "hello" # assign hello
                                         >>> s = "This is a long sentence!"
                                                                                                                                       >>> 11 = [1]*5
   >>> a.upper()
                                         >>> s[::3] # every third letter
                                                                                              declaration of list
                                                                                                                                       >>> 11
    HELLO
                                                                                             >>> 1 = [] # empty list
                                        >>> g = "z"
                                                                                             >>> 1
                                                                                                                                       >>> 12 = [k for k in range(5)]
   >>> a = "HELLO"
                                         >>> 10*8
                                                                                                                                       >>> 12
   >>> a.lower()
                                         '222222222'
                                                                                             >>> 1 = [1, 2, 3] # integers list
                                                                                                                                       [0, 1, 2, 3, 4]
                                                                                             >>> 1
                                                                                                                                       The last command is similar to the
   >>> a
                                         Splitting and concatenation
    HELLO
                                                                                                                                       mathematical definition \{k: k =
                                                                                             >>> 1 = [1.0, 3.0, 3.0] # float list
                                        >>> name = "This is a long sentence."
                                                                                                                                       0.1.2.3.4}.
                                        >>> name.split()
                                                                                                                                       addition of lists
   >>> a = "Hello"
                                         ['This', 'is', 'a', 'long', 'sentence.']
                                                                                             lists can contain anything
   >>> a.swapcase()
                                                                                                                                       >>> 11 = [1.2.3]
                                        >>> name
    PELLUA
                                                                                             >>> 11 = [1,2,3]
                                                                                                                                       >>> 12 = [4,5,6]
                                         'This is a long sentence.'
                                                                                             >>> 12 = ["hello", [], "new"]
   >>> a
                                                                                                                                       >>> 11+12
    'Hello'
                                                                                             >>> 1 = [11, 12]
                                                                                                                                       [1, 2, 3, 4, 5, 6]
                                                                                             >>> 1
   inserting strings
                                                                                              [[1, 2, 3], ['hello', [], 'new']]
   >>> 'Insert here: {}'.format('Inserted string')

                                                       400 (B) (E) (E) (B) (000
                                                                                                                                                 (B) (B) (E) (E) E 990
                                The basics
                                                                                                                          The basics
                                                                                         Tuple
More on lists

    Tuple are essentially uneditable lists. We use round parenthesis.

                                        >>> 1 = [1, 2, 3, 4, 4]

    referencing possible, but no assignment

                                        555 1
   The list class has the following methods: [1, 2, 3, 4, 4]
                                                                                                to be used when list should not be modified.

    append

                                                                                              declaration of list
                                        >>> 1.reverse()
      clear
                                        555 1
                                                                                             >>> 1 = () # empty tuple
      copy
                                         [4, 4, 3, 2, 1]
                                                                                             >>> 1
      count
                                        >>> 1.pop(3)
                                                                                             >>> 1 = (1, 2, 3) # tuple of integers
      extend
                                                                                             >>> 1

    index

                                        >>> 1
                                                                                             >>> 1 = tuple([1.0, 3.0, 3.0]) # conversion of list to tuple
      insert
                                         [4, 4, 3, 1]
                                                                                             555 1
      non
                                        >>> # print every 2nd element
      remove
                                        >>> # start with index 1
      roverce
                                        >>> # go until end of list -1
                                                                                             adding tuples
                                        >>> # the : operation is called slicing
      sort
                                                                                             >>> 1+1
                                        >>> 1[1:-1:2]
                                         [4]
```

    print("x has value 2")
```

#### Listing 5: if\_else\_ex2.pv

```
if x == 1:
    print("x has value 1")
else:
    print("x has another value")
```

# for loop

#### Listing 6: for\_loop.pv

```
for n in range(10):
   print(n)
```

The basics

- Here n ranges from 0 to 9 and is printed after each loop.
- general syntax is range(start, stop, steps)
- start and steps are optional

## Listing 7: for\_loop2.py

```
1 = [0, 1, 'hello', True, False]
for n in 1:
    print(n)
```

```
The basics
```

# for loop (continued)

use enumerate to count the element in the loop

## Listing 8: for\_loop\_en.py

```
= ['one', 'two', 'three', 'four', 'five']
for n, s in enumerate(1):
   print('Item number', n, 'item itself', s)
```

Kevin Sturm

# The basics

#### **Functions**

Let's have a look at an example function.

```
Listing 10: func.py
```

```
def mv func(x):
   x = x + 1.0
   return x
```

- indention in python replaces brackets!!!
- · a function always starts with def
- a return is not mandatory
- without return the function returns None.

### While loop

The syntax of a python while loop is as follows.

```
while statement:
   do stuff
```

"do stuff" is executed as long as statement is true.

The basics

- notice again the indention!
- use break to leave a while loop
- use continue to go to the next loop

#### Listing 9: while\_loop.pv

```
counter = 10
while counter > 0:
   print("counter is", counter)
   counter -= 1
```

# The basics

# Functions (continued)

anonymous functions can be defined using lambda keyword

```
>>> f = lambda x: x**2 # define lambda function f
>>> f(2)
a more complicated example
>>> f = lambda x: x**2 if x < 0 else x**3
>>> f(2)
```

#### Listing 11: lambda\_func.py

```
def f(x):
     if x < 0:
        return x**2
     else:
        return x**3
```

400 (B) (E) (E) (B) (000

10) (B) (E) (E) (B) (0)

make a dictionary with {} and : to signify a key and a value

>>> mv dict = {'kev1':value1.'kev2':value2}

>>> value1 = 1.0

>>> value2 = 2.0

>>> print(my\_dict)

>>> 'key2' in my\_dict

{'key1': 1.0, 'key2': 2.0}

>>> my\_dict['key1'] # access value1

It is possible to give functions optional arguments.

# Listing 12: func\_opt.py

```
def f(x, v=None):
   if v == None:
       return x**2
   else:
       return x**2 + v**2
print(f(1))
print(f(1,2))
```

## 400 (B) (E) (E) (B) (000

Kevin Sturm The basics

sets are unordered lists

Kevin Sturm The basics (B) (B) (E) (E) E 990

#### Sets

# Dictionaries (continued)

#### Accessing the values and the keys

```
>>> # Make a dictionary with fl and : to signify a key and a value
>>> value1 = 1.0
>>> value2 = 2.0
>>> mv dict = {'kev1':value1.'kev2':value2}
>>> print(mv dict.values()) # return values of dictionary
dict_values([1.0, 2.0])
```

Kevin Sturm Python 3

```
>>> print(mv dict.items()) # return items
dict_items([('key1', 1.0), ('key2', 2.0)])
```

```
>>> print(mv dict.kevs()) # return keus
dict kevs(['kev1', 'kev2'])
```

(B) (B) (E) (E) E 990

while

with

pass

raise yield

return

None

nonlocal True

## Math modul

Python key words

and

assert

break else global

class

continue

as

#### Let us consider as an example the math package. >>> import math # import math module and use name "math"

- >>> math.pi
- - >>> del(math) # remove math package
  - >>> import math as m # import math module with name "m"
- >>> m.pi
- >>> del(m)
- >>> from math import pi # import constant pi from math
- >>> pi 3.141592653589793
- >>> from math import pi as pipi # import constant pi from math with name "pipi" >>> pipi

# Importing modules

- import a module with command import module\_name
- a function func in module\_name can be accessed by module\_name.func
- including with different name use import module name as mn
- import specific function: from module name import func
- import everything with from module\_name import \*

# Immutable vs mutable datatypes (continued)

# Immutable vs mutable datatypes

- Python distinguishes two datatypes: mutable and immutable
- immutable: float, int, string, tuple
- mutable: set list dict

The build-in function id(variable) shows the unique identity of a python object.

```
>>> s1 = "CompMath"
>>> s2 = "CompMath"
```

>>> id(s1)

140017699196080 >>> id(s2) 140017699196080

>>> s1 is s2 # check if s1 is s2

True

>>> s1 == s2 # check if s1 has same values as s2 True

The basics

# 400 (8) (8) (8) (8) (9)

Kevin Sturm The basics (B) (B) (E) (E) E 990

## Immutable vs mutable datatypes (continued)

```
>>> 11 = [0.1, "CompMath"]
555 12 = 11
```

>>> id(12) 140017702570248

>>> 11[0] = 0.0 >>> 11 [0.0, 'CompMath']

>>> 12 [0.0, 'CompMath']

#### So I1 and I2 share the same reference. Changing I1 also changes I2. Kevin Sturm Python 3

### Let us now check lists

The basics

>>> 11 = [0.1, "CompMath"] >>> 12 = [0.1, "CompMath"]

>>> id(11) 140017702123272 >>> id(12) 140017702152648

>>> 11 is 12 # check if l1 is 12

>>> 11 == 12 # check if l1 has same values as l2

So both lists are different, but have exactly the same values.

# Immutable vs mutable datatypes (continued)

So how can we copy a list?

>>> 11 = [0.1, "CompMath"] >>> 12 = 11[:] # this generates a copy of l1

>>> 11 is 12 # check if s1 is s2

>>> 11 == 12 # check if s1 has same values as s2 True

>>> id(11) 140017702152648 >>> id(12)

140017702123272

# a is bysa==b

- if list elements are mutable itself the previous copying does not work as one might expect
- >>> change = [0, 0, 0] >>> 11 = [1, 2, change]
- >>> 12 = 11[:] # change is not copied here
- In this case one can use deepcopy of the module copy. >>> change = [0, 0, 0]
- >>> 11 = [1, 2, change]
- >>> import copy
- >>> 12 = copv.deepcopv(11)

- The way python 3 is implemented the integer numbers [-5, 256] are cached. For integers in this range python only returns a reference to the same element.
- >>> a = 1 >>> c = 1000 >>> h = 1 >>> d = 1000 >>> id(a) >>> id(c) 140017702160560 >>> id(b) >>> id(d) 94324142568192 140017702161520 >>> a is b ## a and b same >>> c is d ## two different references >>> a == b >>> c == d

#### 400 (B) (E) (E) (B) (000

Kevin Sturm The basics

Kevin Sturm The basics

(B) (B) (E) (E) E 990

# Local vs global variables - example

# Local vs global variables

How to figure our which variables are defined so far?

- · dir() list defined variables in scope
- . globals() dict of global variables
- . locals() dict of local variables in scope (including values)

# Listing 13: dirs.pv

```
b = 0.
def f(x):
    a = 0.0
    print("local variables in f", locals())
    print("local variables f", dir())
    return x
print("local variables in current scope", locals())
print(f(0.1))
```

Python 3

Classes

Classes

# Listing 14: class\_ex.py

```
class simple:
   pass
```

- keyword class defines a class with name simple
- keyword pass means that the class simple does nothing

## Listing 15: class\_ex2.py

```
class simple_two:
    a = 0.1
    s = "hello"
t = simple two() # define class instance
print(t.a) # print variable a
```

The basics

- keyword class defines a class with name simple
- keyword pass means that the class simple does nothing

The basics

### 400 (B) (E) (E) (B) (000

```
Kevin Sturm
 The basics
```

# Classes - constructor

#### Listing 16: class\_construct.py

```
class test:
   def init (self, a = 0.0): # constructor
       self.a = a
C1 = test(0.1) \# create instance C1 with value a = 0.1
C2 = test() # create instance C2 with default value
print(C1.a) # print value of variable a
```

- a class constructor is defined by \_\_init\_\_, which is called upon initialisation of the class Kevin Sturm Python 3
- the class test has an optimal argument a, which is by default 0.0

# Classes - methods

### Listing 17: class\_method.pv

(B) (B) (E) (E) E 990

```
class test:
   def init (self):
       print("This is the constructor.")
   def func(self):
       print("This is the func.")
C = test() # create instance C
C.func() # call func()
```

Kevin Sturm Python 3

 the first argument of a method (here func(self)) must be self function is accessed via C.func()

```
The basics
```

# What is self?

Classes - methods

# Listing 18: class\_method2.pv

```
class test:
   def __init__(self):
       print("This is the constructor.")
   def func2(self, b):
       print("This is func2 with b = {}".format(b))
C = t.est()
C.func2(0.3) # call func2(0.3)
```

the first argument of a method (here func(self)) must be self (see next slide)

Kevin Sturm The basics

```
class test:
```

C.we call self() print("This is C", C)

C = test()

The basics

The basics

• the name does not have to be "self", but it is recommended the first argument of a method in a class is always self

print("This is the constructor.")

print("This is self", self)

Listing 19: self.py

self is basically a reference to the class instance

# Inheriting classes

statement-N

As in C++ we can inherit classes. The basic syntax is as follows:

```
class Derived_ClassName(Base_ClassName):
   statement-1
```

Inheriting classes: example

def \_\_init\_\_(self):

def we call self(self):

#### Listing 20: inherit.pv

```
class Base_Class:
   def f(self, x):
       return v
class Derived Class(Base Class):
   def g(self, x, y):
       return x + v
```

- Base Class() contains the functions f(x)
- Derived\_Class extends Base\_Class() by g(x, y)

400 (B) (E) (E) (B) (000

```
we can read a file with open("filename", 'r')
```

We now want to read the file

#### Listing 21: readme.txt

```
This is CompMath.
We want to read this file.
```

```
>>> file = open("code/code_lec2/readme.txt", 'r')
>>> print(file.readlines())
['This is CompMath.\n', '\n', 'We want to read this file.\n']
>>> file.close()
```

# we can write to a file with open("filename", 'w')

The basics

- · if "filename" is not there it will be created
- file = open("code/code\_lec2/writeme.txt", 'w+') file.write("We write this into writeme.txt") file.close()

Kevin Sturm The basics

The basics

Kevin Sturm

(B) (B) (E) (E) E 990

# Further options of ()

# Reading and writing lines

The function open has the following options. (Taken from help(open)).

```
open for reading (default)
open for writing, truncating the file first
create a new file and open it for writing
open for writing, appending to the end of the file if it exists
binary mode
text mode (default)
open a disk file for updating (reading and writing)
universal newline mode (deprecated)
```

Now suppose we want to add text to the beginning of the file prepend.txt

```
file = open("prepend.txt", 'a+') # open file prepend.txt
file.seek(0) # start at beginning of file
s = ["This text should go at the beginning."]
file.writelines(s)
file.close()
```

#### What is a doc string?

doc-string is convenient way do describe document modules, functions, classes,

#### How do we define a doc string?

a doc-string has the syntax """ documentation here """

#### How do we use a doc string?

The doc string can be accessed with . doc .

## Listing 22: doc\_string.pv

```
""" This is a doc string. """
def f(x, y = 0.0):
    This function adds numbers x and v.
    The variable v is optional. Default is v = 0.0
    return x + v
#print("call doc string with f. doc : ". f. doc )
print("alternatively use help(f):", help(f))
```

Kevin Sturm

The basics

The basics

#### 400 (B) (E) (E) (B) (000

Kevin Sturm The basics

Decorators - Example 1

#### Decorators

The basic decorator code structure is as follows:

```
def decor(func):
   def inner():
       func()
   return inner
```

Usage:

dec = decor(func)

- decor is a wrapper function essentially a function that returns a function
- the decorator gets as argument a function (func()) and returns another function (inner())
- the "actual" coding happens inside the inner function

#### Listing 23: decorator\_.pv

```
from math import exp
def f(x, y):
    return exp(x*y) + y
def deco(func):
    v = 0.0 \# define value for v
    def f1(x):
        return func(x, v)
    return f1
```

# Listing 24: decorator2\_.py

```
from math import exp
def f(x, v):
    return exp(x*v) + v
def deco(func, y): # decorator has y as argument
    def f1(x):
       return func(x, y)
    return f1
de = deco(f, 5)
print(de(0.1))
```

#### Listing 25: decorator3\_.py

The basics

```
from math import sin, cos
 def func_comp(fun1, fun2):
      def f1(x):
         return fun1(fun2(x))
      return f1
 de = func_comp(cos, sin)
 print(de(0.1))
```

Kevin Sturm

The basics

# 400 (B) (E) (E) (B) (000

Kevin Sturm The basics

# (B) (B) (E) (E) E 990

# Recursion without loops

## Suppose we want to implement the factorial n!! A loop approach would be as follows:

#### Listing 26: factorial\_loop.py

```
def fac(n):
    val = 1
    for k in range(1, n+1):
       val = val*k
    return val
print(fac(10))
```

## Recursion without loops

As second approach without loops is

## Listing 27: factorial\_loop\_free.pv

```
def fac(n):
    if n == 1:
        return 1
    else:
        return n*fac(n-1) ## function fac called with n-1
print(fac(10))
```

using second approach avoid calling function multiple times!! Consider

$$x_{n+1} = \frac{1}{2} \left( x_n + \frac{1}{x_n} \right).$$

#### Listing 28: babylon\_bad.py

```
def babylon(n):
   x0 = 10
   if n == 1.
       return x0
   else:
       return (1/2)*(babylon(n-1) + 2/babylon(n-1))
```

problem: if  $a_n$  is number of function calls, then  $a_n = 2a_{n-1}$  and hence  $a_n = 2^n$  function calls are need. In total to compute recursion at stage n we need  $\sum_{\ell=0}^{n} a_{\ell} = 2^{n+1} - 1$ . 10110101010

Kevin Sturm The basics

\*args and \* \* kwargs

- sometimes the number of arguments a function gets is unknown. Then we can use \*arg and \*\*kwargs.
- · kwargs keyword arguments; args normal arguments
- The actual names args and kwargs are irrelevant, we could also use \*va, only the star \* matters; same for kwargs.

Basic syntax is as follows:

```
def f(farg, *args, **kwargs):
   # do something with args, farg and kwargs
```

- inside the function f args will be a tuple and kwargs a dictionary.
- the order of farg, args and kwargs matters: positional argument follows keyword argument

using second approach avoid calling function multiple times!! Consider

$$x_{n+1} = \frac{1}{2} \left( x_n + \frac{1}{x_n} \right).$$

### Listing 29: babylon\_good.py

```
def babylon(n):
   x0 = 10
   if n == 1:
       return v0
   else:
       xn = babvlon(n-1)
       return (1/2)*(xn + 2/xn)
```

better: here we have  $a_n=a_{n-1}$ , so  $a_n=a_0=1$  and hence in total  $\sum_{\ell=0}^n a_\ell=n+1$ .

Kevin Sturm The basics

\*args- example 1

#### Listing 30: args\_ex1.pv

```
def f(*args):
      print(type(args))
      print(args)
  f(1,2,3)
 f([1,],3,4,'hello')
```

- To illustrate \*args, we want implement the polynomial  $p(x) = a_0 x^0 + \cdots + a_1 x + a_0.$
- The number n of coefficients  $a_0, \ldots, a_n \in \mathbb{R}$  is variable; hence we can define a python function polynom(x,\*args)

```
400 (B) (E) (E) (B) (000
Kevin Sturm
 The basics
```

## \*kwargs - example 1

With kwargs we can give a function an arbitrary number of optional keyword arguments.

### Listing 32: kwargs\_ex1.py

```
def f(**kwargs):
   print(type(kwargs))
   print(kwargs)
f(a=1, b=2, c=3)
d = {'a':1, 'b':1, 'c':1}
f(**d)
```

# Listing 31: args\_ex2.pv

```
def polynom(x, *args):
    n = len(args)
    val = 0.0
    print(type(args))
    for k in range(n):
        val += args[k] *x**k
    return val
a = (1, 2, 3, 4)
print(polynom(0.1, *a))
print(polynom(0.1, 1, 2, 3, 4))
```

# Kevin Sturm The basics

## Measuring time - in ipython shell

- in the ipython shell one can use time to measure the time a function call takes
- usage: %time sin(1) to find the time it took to eval sin at 1.
- to get more accurate average use %timeit which runs 1000000 loops

The basics

# Measuring time

to measure time of code segments we can use the time module

Listing 33: measuring\_time.pv

```
import time # time module
def tic(): # start measuring time
   global start
   start = time.time()
def toc(): # end measuring time
   if 'start' in globals():
       print("time: {}.".format(str(time.time()-start)))
   else.
       print("toc(): start time not set")
```

(D) (B) (E) (E) E 990 Kevin Sturm

# What is time time()

 The function time.time() return time since epoch in second. For Unix system, January 1, 1970, 00:00:00 at UTC is epoch.

The basics

#### We test this:

```
>>> import time
>>> time.time() # epoch time in second
>>> time.time()/(60*60*24*365.25) # convert in years
49 33751996876516
>>> T = time.time()/(60*60*24*365.25)
```

>>> 2019 - T 1969.6624800312309

# Measuring time (continued)

Let us now use the functions tic and toc to measure for instance the time to evaluate sin and cos

#### Listing 34: measuring\_time.pv

The basics

```
from measure_time import tic, toc
from math import sin, cos
sin(1.0)
cos(1.0)
toc()
```

10) (B) (E) (E) (B) (0) Kevin Sturm The basics

Measuring time of function evals

- we can now combine our knowledge of decorators, \*args and \*\*kwargs and the time measurement to write a function which measures the execution time of a
- rather than putting tic and toc before and after a function in the code, we want to have a function calculate time(func) which measures the execution

# Listing 35: measuring\_time.py

```
import time
def calculate_time(func):
   def inner1(*args, **kwargs):
       begin = time.time()
       func(*args, **kwargs)
       end = time.time()
       print("Total time taken in : ", func.__name__, end
           - begin)
   return inner1
```

# Listing 36: measuring\_time2.py

```
from measure_time_func import calculate_time
 import math
# test how long it takes to eval sin
SIN = calculate time(math.sin)
SIN(10)
```

Kevin Sturm

The basics

# Kevin Sturm The basics

# Call by value

# Call by reference vs. call by value

# · function calls in python are call by reference if the object that is passed is

· for immutable objects (e.g., float, tuple, int) only a copy is passed

#### Listing 37: func\_call\_by\_ref.py

```
1 1 = [1,2]
print('id', id(1)) # print identity of 1
 print('1', 1, '\n') # print list 1
 def add(1 ):
     1_ += [1]
 add(1) # call add()
 print('id', id(1))
 print('1', 1)
```

10) (B) (E) (E) (B) (0)

The basics

Kevin Sturm

## Listing 38: func\_call\_by\_val.py

```
a = 1
print('id', id(a))
print('a', a)
def add(a):
    a += 1
print('id', id(a))
print('a', a)
```

```
    How to evaluate a function f(x) for a list of values, say,

     1 = [1, 2, 3, 4, 4, 4]?

    solution: use map(f, 1)

>>> f = lambda x: x**4
>>> 1 = [1, 2, 3, 4, 4, 4]
>>> map(f, 1)
<map object at 0x7f586960ce10>
>>> print(list(map(f.1)))
[1, 16, 81, 256, 256, 256]
```

The numpy package

400 (B) (E) (E) (B) (000 Kevin Sturm

The numpy package

The numpy package

The numpy package

The numpy module offers the following functionalities:

- a powerful N-dimensional array object
- sophisticated (broadcasting) functions
- basic linear algebra functions
- basic Fourier transforms
- sophisticated random number capabilities
- · tools for integrating Fortran code
- tools for integrating C/C++ code

The numpy package is import by import numpy as np

Numpy arrays

arrays are defined by a = np.array([], dtype = datatype)

Kevin Sturm

- dtvpe is optional
- · each entry of an array has to hold same data type (unlike python arrays)
- example: a = np.array([1,2], dtype = float) or shorter
- a = np.array([1.,2.])

# Concatenating matrices

#### We can "glue" matrices together with np.concatentate.

```
>>> A = np.array([[1,2,3],[2,2,2]])
>>> A
array([[1, 2, 3],
>>> B = np.ones((3,2))
>>> R
>>> AB = np.concatenate((A.B.T), axis=1)
>>> AB
array([[1., 2., 3., 1., 1., 1.],
```

[2., 2., 2., 1., 1., 1.])

- · functions can be evaluated at arrays (similarly to map with list)
- return value is of the shape of input array
- this avoids loops and is fast

Arrays and functions

```
>>> def f(x):
       return x**2
>>> a = np.array([[1,2,3], [2,3,4]])
>>> print(f(a))
FF 1 4 91
[ 4 9 16]]
```

400 (B) (E) (E) (B) (000

# The numpy package

# Arrays and functions (continued)

```
>>> def f(x):
        return x**2
>>> a = np.array([[1,2,3], [2,3,4]])
>>> print(f(a))
[[ 1 4 9]
[ 4 9 16]]
```

This code corresponds to

$$f(a) = \begin{pmatrix} f(a_{00}) & f(a_{01}) & f(a_{02}) \\ f(a_{10}) & f(a_{11}) & f(a_{12}) \end{pmatrix}$$

# Arrays and functions (continued)

```
>>> def f(x, y):
       return x**2 + v**2
>>> a = np.array([[1,2,3], [2,3,4]])
>>> b = np.array([[0,5,6], [0,2,4]])
>>> print(f(a,b))
[[ 1 29 45]
[ 4 13 32]]
```

This code corresponds to

$$f(a,b) = \begin{pmatrix} f(a_{00}, b_{00}) & f(a_{01}, b_{01}) & f(a_{02}, b_{02}) \\ f(a_{00}, b_{00}) & f(a_{01}, b_{01}) & f(a_{02}, b_{02}) \end{pmatrix}.$$

400 (B) (E) (E) (B) (000 Kevin Sturm

Kevin Sturm

## Arrays and functions (continued)

This code corresponds to

$$f(\mathbf{a},b) = \left(f\left(\begin{pmatrix} a_{00} \\ a_{10} \end{pmatrix}, \begin{pmatrix} b_{00} \\ b_{10} \end{pmatrix}\right) \quad f\left(\begin{pmatrix} a_{01} \\ a_{11} \end{pmatrix}, \begin{pmatrix} b_{01} \\ b_{11} \end{pmatrix}\right) \quad f\left(\begin{pmatrix} a_{02} \\ a_{12} \end{pmatrix}, \begin{pmatrix} b_{02} \\ b_{12} \end{pmatrix}\right)\right).$$

```
>>> [f(a[:.0],b[:.0]), f(a[:.1],b[:.1]), f(a[:.2],b[:.2])]
[1, 53, 121]
```

>>> a = time() >>> arr1 = f(r)

0.01756572723388672

## Arrays and functions (continued)

- What is the advantage of arrays over python lists? Answer: speed
- Reason: numpy arrays are saved into contiguous blocks in the memory, while python lists are scattered over the memory. (Note: this is not true for dtype = object)

```
>>> r = np.random.rand(10000) # Random array of length 10000
>>> from time import time
>>> def f(x):
       return x**2 + np.sin(x**3)
```

```
>>> print(time() - a)
>>> a = time()
```

(B) (B) (E) (E) E 990

# Arrays and functions (continued)

some functions need to be rewritten to support evaluation on arrays

For instance the function:

$$\Theta(x) := \left\{ \begin{array}{ll} 1 & x > 0 \\ 0 & x < 0 \end{array} \right.$$

In this case no where (cond. vall. val2) is helpful, which returns vall if cond is True and val2 if cond is False

```
>>> a = np.array([1,2,-3])
                                   >>> a = np.array([1,2,3])
>>> def theta1(x):
                                   >>> def theta2(x):
       1f v>0.
                                           return np.where(x>0.1.0)
            return 1
                                   >>> theta2(a)
        else:
```

return 0 >>> #theta1(a) gives error

# Broadcasting arrays

- typically only arrays of the same dimension are added; however it is also possible to add arrays of different dimension
- in this case a new array is created and the dimension missing is "filled up"

What happens is for instance the following:

$$\begin{pmatrix} a_1 & a_2 & a_2 \end{pmatrix} + \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} = \begin{pmatrix} a_1 & a_2 & a_3 \\ a_1 & a_2 & a_3 \\ \end{pmatrix} + \begin{pmatrix} b_1 & b_1 & b_1 \\ b_2 & b_2 & b_2 \\ b_3 & b_3 & b_3 \end{pmatrix}$$

Kevin Sturm

400 (B) (E) (E) (B) (000 Kevin Sturm

The numpy package

array([1, 1, 1])

The numpy package More element wise operations

# Broadcasting arrays

#### Now why is this useful? For instance:

>>> 
$$a = np.array([1,2,3,1])$$
  
>>>  $a = a + 1 \# new array is created with each element +1>>>  $a$   
array([2, 3, 4, 2])$ 

#### The same broadcasting works for - and \*. For instnace

array([[1. 2. 3]. ſ1, 2, 3],

array([3, 4, 5, 3])

We can compare matrices element wise. >>> A = np.array([[1,2,3],[2,3,4]])

Kevin Sturm Python 3

# The numpy package Tridiagonal matrices

Example of a tridiagonal matrix

## Diagonal matrices

- create diagonal matrices with np.diag(a)
- extract diagonal of matrix with np.diag(A)

```
>>> a = np.array([(-k)**k for k in range(4)])
>>> a
arrav([ 1, -1, 4, -27])
```

# >>> diag(a)

#### [ 0, 0, 4, 0], [ 0. 0. 0. -2711)

400 (B) (E) (E) (B) (000

Kevin Sturm The numpy package

array([[ 2., -1., 0., 0.], [-1., 2., -1., 0.], [ 0., -1., 2., -1.], [ 0.. 0.. -1.. 2.11)

>>> T = diag(a,0)+diag(b,-1)+diag(b,1)

Kevin Sturm The numpy package

 $T_N = \begin{pmatrix} 2 & -1 & 0 \\ -1 & \cdot & \cdot & \\ & \cdot & \cdot & -1 \\ 0 & & -1 & 2 \end{pmatrix}$ 

(B) (B) (E) (E) E 990

Example

Block matrices

- · Let A, B, C, D be matrices. Then in numpy with block we can define the new matrix  $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ .
- If we only want  $\begin{pmatrix} A & B \end{pmatrix}$  or  $\begin{pmatrix} A \\ C \end{pmatrix}$ , we can also use vstack or hstack.

```
>>> B = ones((2.2))
                                    >>> B = 4*eve(2)
>>> C = B.copy()
                                    >>> hstack([B,B])
>>> A = array([[1,2],[1,2]])
                                    array([[4., 0., 4., 0.],
>>> D = A.copv()
                                           [0., 4., 0., 4.]1)
>>> block([[A.B].[C.D]])
                                    >>> vstack([B.B])
array([[1., 2., 1., 1.].
                                    array([[4.. 0.].
       [1., 2., 1., 1.],
                                           [0., 4.],
```

Reshaping arrays

>>> a = 2\*ones(4)

>>> b = -ones(3)

>>> T

- shape of an array a can be displayed by a shape or np shape(a).
- for reshape an array use a.reshape(shape), where shape is a tuple

```
>>> a = np.array([[1,2,3],[0,0,5]])
                                        >>> a = np.array([[1,2,3],[0,0,5]])
>>> a.shape # print shape
                                        >>> a.reshape((1.6))
                                        array([[1, 2, 3, 0, 0, 5]])
>>> a.T # transpose array
                                        >>> a.reshape((6,1))
       [2, 0],
                                        array([[1],
>>> a.T.shape # shape of transposed
                                               [3].
```

[4., 0.],

The numpy package

## More functions of array

```
>>> A = np.arrav([1,1])
>>> dir_A = [s for s in dir(A) if s[0] != '_']
>>> for s in range(0.len(dir A)-7.7):
           print(dir_A[s:s+7])

#### linalg module

- linalg is a submodule of numpy, which provides basic linear algebra tools
- it is recommended to rather use the linear algebra package of scipy

#### Typing help(numpy.linalg) shows:

- norm Vector or matrix norm - inv Inverse of a square matrix
- Solve a linear system of equations - solve
- det Determinant of a square matrix
- Istsa Solve linear least-squares problem
- pinv Pseudo-inverse (Moore-Penrose) calculated using a singular value decomposition
- matrix\_power Integer power of a square matrix

#### More functions of the numpy module

The numpy package

A list of all functions in the numpy package can be obtained by typing dir(numpy) in the ipython shell.

For instance the names of (for space reasons here) of all functions starting with 's':

- >>> import numpy
- >>> dir\_s = [s for s in dir(numpy) if s[0] == 's'] >>> for k in range(0,len(dir\_s),5):
  - print(dir s[k:k+5])
  - ['s\_', 'safe\_eval', 'save', 'savetxt', 'savez']
- ['savez\_compressed', 'sctype2char', 'sctypeDict', 'sctypeNA', 'sctypes'] ['searchsorted', 'select', 'set\_numeric\_ops', 'set\_printoptions', 'set\_string\_f ['setbufsize', 'setdiffid', 'seterr', 'seterrcall', 'seterrobj']
- ['setxorid', 'shape', 'shares memory', 'short', 'show config']
- ['sign', 'signbit', 'signedinteger', 'sin', 'sinc'] ['single', 'singlecomplex', 'sinh', 'size', 'sometrue']
- ['sort', 'sort complex', 'source', 'spacing', 'split']
- ['sgrt', 'square', 'squeeze', 'stack', 'std']
- ['str', 'str0', 'str\_', 'string\_', 'subtract']
- ['sum', 'swapaxes', 'sys']

Kevin Sturm The scipy package

Kevin Sturm The scipy package scipy linalg - solving linear systems

イロン・ボン・ボン・モー カスの

# Scipy vs. Numpy?

- Numpy should do: indexing, sorting, reshaping, basic elementwise functions
- Scipv should do: numerical algorithms
- · Problem: Numpy is backward compatible; hence it also contains numerical algorithms
- But: Scipv has usually more fully fledged algorithms

SciPy imports all the functions from the NumPy namespace.

- Most important functions:
  - inv Find the inverse of a square matrix
  - solve Solve a linear system of equations
  - · det Find the determinant of a square matrix norm - Matrix and vector norm

  - Istsg Solve a linear least-squares problem
  - pinv Pseudo-inverse (Moore-Penrose) using Istsq
  - pinv2 Pseudo-inverse using svd
  - kron Kronecker product of two arrays

Answer: it depends on the structure of A.

 'pos' → LL<sup>T</sup> (or Cholesky) factorisation 'sym' → LDL<sup>T</sup> factorisation • 'her' → IDI<sup>H</sup> facorisation

linalg.solve(A,b, assume\_a = 'opt')

'gen' → LU factorisation

· Question: What method does linagl.solve call to solve the system?

You can tell linalg.solve what type of matrix it is via assume\_a.

- Let  $A \in \mathbb{R}^{d \times d}$  and  $b \in \mathbb{R}^d$ . Then we can solve Ax = b with scipy as follows:
- >>> from scipy.linalg import solve
- >>> A = np.array([[0,2,3],[2,2,2],[2,3,4]])
- >>> b = np.array([1,1,1])
- >>> print(x)
- >>> norm(A0x-b)

- >>> x = solve(A,b)
- [-0.5 2. -1. ]
- >>> # test if correct

Solve option - LAPACK

## scipy linalg - decompositions

 The function linalg.solve calls the LAPACK functions ?GESV. ?SYSV. ?HESV. and ?POSV.

- LAPACK is a package written in Fortran 90 provides routines for
  - solving systems of simultaneous linear equations
  - · least-squares solutions of linear systems of equations
  - eigenvalue problems
  - singular value problems.

These functions allow different decompositions A = CD of a matrix  $A \in \mathbb{R}^{d \times d}$  into to matrices  $C \in \mathbb{R}^{d \times d}$  and  $D \in \mathbb{R}^{d \times d}$ .

- LU decomposition of a matrix
- lu solve - Solve Ax=b using back substitution with output of lu\_factor
- svd - Singular value decomposition of a matrix svdvals - Singular values of a matrix
- null\_space
- Construct orthonormal basis for the null space of A using svd ы - LDL.T decomposition of a Hermitian or a symmetric matrix
- cholesky - Cholesky decomposition of a matrix
- OR decomposition of a matrix schur
- Schur decomposition of a matrix - Hessenberg form of a matrix

Python 3

>>> A = array([[1,2,3],[3,3,3],[3,3,3]])

Given  $A \in \mathbb{R}^{d \times d}$  (or  $\in \mathbb{C}^d$ ) we want solve the eigenvalue problem: find  $(\lambda, \nu) \in \mathbf{C} \times \mathbf{C}^d$ , such that  $A\nu = \lambda \nu$ .

- · eig Find the eigenvalues and eigenvectors of a square matrix
- · eigvals Find just the eigenvalues of a square matrix
- eigh Find the e-vals and e-vectors of a Hermitian or symmetric matrix
- eigvalsh Find just the eigenvalues of a Hermitian or symmetric matrix
- · eig\_banded Find the eigenvalues and eigenvectors of a banded matrix
- eigvals\_banded Find just the eigenvalues of a banded matrix

```
>>> [D, V] = linalg.eig(A)
array([-1.10977223, 8.10977223, 0.
>>> V
array([[-0.85872789, 0.44526277, 0.40824829],
      [ 0.36234405, 0.63314337, -0.81649658],
      [ 0.36234405, 0.63314337, 0.40824829]])
>>> A = array([[0, -1],[0,1]])
>>> linalg.eig(A)
(array([0., 1.]), array([[ 1.
                                    . -0.70710678].
      Γο.
```

# Solving singular linear system

If A is not regular  $A^{-1}$  does not exist. However one can always solve

$$\min_{x \in \mathbb{R}^d} ||Ax - b||_2^2$$

which is called least square problem/(Problem der kleinsten Quadrate). In scipy this can be solved with linalg.lstsq(A,b).

```
>>> A = array([[1,2,3],[3,3,3],[3,3,3]])
>>> b = np.array([1,2,1])
>>> x = linalg.lstsq(A,b)[0]
>>> x
```

Solving singular linear system: pseudo inverse

Kevin Sturm

Let  $b \in \mathbb{R}^m$ . The pseudo inverse of a matrix  $A \in \mathbb{R}^{m \times n}$  is denote by  $A^+$  and defined by its action  $A^+b := x$ , where  $x \in \mathbb{R}^n$  is the solution to

$$\min_{x \in \mathbb{R}^n} ||Ax - b||_2^2$$

with minimal norm  $||x||_2$ .

 In scipy the pseudo inverse is defined by scipy.linalg.piny or scipy.linalg.pinv2.

Kevin Sturm

 The first method uses scipy.linalg.lstsq and second computes uses the singular value decomposition of A.

Python 3

### For example let $\hat{A} \in \mathbb{R}^{d \times d}$ be invertible and define

$$A := \begin{pmatrix} \hat{A} & 0 \\ 0 & 0 \end{pmatrix} \in \mathbb{R}^{(d+\ell) \times (d+\ell)}$$
.

Then

$$A^+ = \begin{pmatrix} \hat{A}^{-1} & 0 \\ 0 & 0 \end{pmatrix}$$

 If the matrix A ∈ R<sup>m×n</sup> is injective, then A<sup>T</sup>A is injective and thus invertible. • We have  $A^+ = (A^T A)^{-1} A^T : \mathbb{R}^m \to \mathbb{R}^n$ .

## Example 2

#### Consider for instance

$$A = \begin{pmatrix} 1 & 0 \\ 2 & 0 \\ 1 & 1 \end{pmatrix}, \ A^\top = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix} \quad \Rightarrow \quad A^\top A = \begin{pmatrix} 6 & 1 \\ 1 & 1 \end{pmatrix}.$$

Hence

$$(A^{\top}A)^{-1} = \frac{1}{5}\begin{pmatrix} 1 & -1 \\ -1 & 6 \end{pmatrix} \Rightarrow A^{+} = \frac{1}{5}\begin{pmatrix} 1 & 2 & 0 \\ -1 & -2 & 5 \end{pmatrix}.$$

# Solving singular linear system: pseudo inverse

#### In scipy the pseudo inverse can be computed via scipy.linalg.piny.

```
The scipy package
```

# Solving singular linear system: pseudo inverse

```
>>> A = np.zeros((3,3))
>>> A_ = np.array([[1,2],[2,1]])
>>> A[0:2,0:2] = A_
>>> b = np.array([1,2,1])
>>> pinv(A)@b
array([ 1.00000000e+00, -2.22044605e-16, 0.00000000e+00])
>>> lstsq(A,b)[0]
array([ 1.00000000e+00, -1.16957102e-16, 0.00000000e+00])
```
